Eucalyptus Overview

Eucalyptus is open source software for building AWS-compatible private and hybrid clouds. As an Infrastructure as a Service product, Eucalyptus allows you to flexibly provision your own collections of resources (both compute and storage), on an as-needed basis.

Whether you're looking for an on-premise complement to your public cloud setup, or already have a virtual data center and now want to move into a private or hybrid cloud setup, Eucalyptus can help you get started today. Download Faststart and have your cloud up and running in half an hour, or take advantage of Eucalyptus' seamless interoperation with Amazon Web Services' EC2 and S3 public cloud services, for an enterprise-grade hybrid cloud platform out of the box.

Who Should Read this Guide?

This guide is for Eucalyptus users who wish to run application workloads on a Eucalyptus cloud.

What's in this Guide?

This guide contains instructions for users of the Eucalyptus cloud platform. While these instructions apply generally to all tools capable of interacting with Eucalyptus, such as the Eucalyptus Management Console or the AWS S3 toolset, but the primary focus is on the use of Euca2ools (Eucalyptus command line tools). The following is an overview of the contents of this guide.

How do I ...?	Related Topic
Begin using and configuring Eucalyptus	Getting Started
Run and control with virtual machine (VM) instances	Using Instances
Use Eucalyptus' elastic block storage	Using EBS
Apply tags and filters	Using Tags and Filters
Manage access for groups and users	Managing Access
Understand the Eucalyptus VM networking and security features	Using VM Networking and Security
Use Eucalyptus' Auto Scaling features	Using Auto Scaling
Use elastic load balancing	Using Elastic Load Balancing
Generate metrics about my cloud	Using CloudWatch
Use scalable object storage	Using Object Storage
Use CloudFormation	Using CloudFormation
Use Virtual Private Cloud	Using Virtual Private Cloud

Eucalyptus Features

Eucalyptus offers ways to implement, manage, and maintain your own collection of virtual resources (machines, network, and storage). The following is an overview of these features.

AWS API compatibility

Eucalyptus provides API compatibility with Amazon Web Services, to allow you to use familiar tools and commands to provision your cloud.

Block- and bucket-based storage abstractions

Eucalyptus provides storage options compatible with Amazon's EBS (block-based) and S3 (bucket-based) storage products.

Self-service capabilities

Eucalyptus offers a Management Console, allowing your users to request the resources they need, and automatically provisioning those resources where available.

Web-based Interface

The Eucalyptus Management Console is accessible from any device via a browser. The Console initial page provides a Dashboard view of components available to you to manage, configure, provision, and generate various reports.

Resource Management

Eucalyptus offers tools to seamlessly manage a variety of virtual resources. The following is an overview of the types of resources your cloud platform.

SSH Key Management

Eucalyptus employs public and private keypairs to validate your identity when you log into VMs using SSH. You can add, describe, and delete keypairs.

Image Management

Before running instances, someone must prepare VM images for use in the cloud. This can be an administrator or a user. Eucalyptus allows you to bundle, upload, register, describe, download, unbundle, and deregister VM images.

Linux Guest OS Support

Eucalyptus lets you run your own VMs in the cloud. You can run, describe, terminate, and reboot a wide variety of Linux-based VMs that were prepared using image management commands.

Windows Guest OS Support

Eucalyptus allows you to run, describe, terminate, reboot, and bundle instances of Windows VMs.

IP Address Management

Eucalyptus can allocate, associate, disassociate, describe, and release IP addresses. Depending on the networking mode, you might have access to public IP addresses that are not statically associated with a VM ([elastic IPs](#)). Eucalyptus provides tools to allow users to reserve and dynamically associate these elastic IPs with virtual machines.

Security Group Management

Security groups are sets of firewall rules applied to VMs associated with the group. Eucalyptus lets you create, describe, delete, authorize, and revoke security groups.

Volume and Snapshot Management

Eucalyptus allows you to create dynamic block volumes. A dynamic block volume is similar to a raw block storage device that can be used with virtual machines. You can create, attach, detach, describe, bundle, and delete volumes. You can also create and delete snapshots of volumes and create new volumes from snapshots.

Document version: Build 30 (2020-12-03 17:50:50 UTC)

Getting Started

This section helps you get started using your Eucalyptus cloud, and covers setting up your user credentials, installing and configuring the command line tools, and working with images and instances.

As a cloud user, you can access the Eucalyptus cloud using a command line interface such as Euca2ools, or using a web-based interface such as the Eucalyptus Management Console. You can switch between them freely. What you create in one will be accessible through the other.

To access Eucalyptus via the command line tools, you need keys for Euca2ools. To access Eucalyptus with the Management Console, you'll need a password for the Management Console. Talk to your cloud administrator to get your keys and passwords.

Getting Started with the Eucalyptus Management Console

This section helps you get started using your Eucalyptus cloud with the Eucalyptus Management Console.

To access Eucalyptus with the Management Console, you'll need a password for the Management Console. Talk to your cloud administrator to get your keys and passwords.

Console Login

This screen allows you to log in to the Eucalyptus Management Console with either your Eucalyptus or your Amazon Web Services account. If you've forgotten your password, don't have login credentials, or do not know the URL for the Eucalyptus Management Console for your Eucalyptus account, please contact your system administrator.

1. Navigate to the Eucalyptus Management Console by typing the URL of the Management Console into your browser's navigation bar. The URL of the Eucalyptus Management Console depends on how the console was installed in your cloud; see your system administrator for the specific URL for your installation.
2. Follow the appropriate instructions below for logging into either your Eucalyptus or your Amazon Web Services cloud.

Log in to your Eucalyptus cloud

This area of the login dialog allows you to log in to your Eucalyptus cloud.

1. Click the **Log in to Eucalyptus** tab.
2. Type your account name into the **Account name** text box.
3. Type your user name into the **User name** text box.
4. Type your password into the **Password** text box.
5. Click the **Log in to Eucalyptus** button.

Log in to your Amazon Web Services cloud

This area of the login dialog allows you to log in to your Amazon Web Services cloud.

1. Click the **Log in to AWS** tab.
2. **Note:** To obtain your AWS security credentials, go to Amazon's [Your Security Credentials](#) page.

Enter your AWS access key ID into the **Access key ID** text box.

3. Enter your AWS secret access key into the **Secret access key** text box.
4. Click the **Log in to AWS** button.

Launch and Connect to an Instance with the Management Console

To launch an instance:

1. Click on the **Launch Instance** button on the main console page:

Eucalyptus

2. Select an image from the list (for this example, we'll select a CentOS image), then click the **Next** button:

Eucalyptus

[Home](#) / [Instances](#) / Launch instance

Launch new instance

Launch Instance

Cancel

Or: [Select advanced options](#)

- b) Type the name of your new key pair into the **Name** text box, and then click the **Create and Download** button:

The screenshot shows the 'Create key pair' dialog box within the AWS Management Console. The breadcrumb navigation at the top reads 'Home / Instances / Launch instance'. The dialog title is 'Create key pair'. Below the title is a instruction: 'Save the downloaded private key file in a place you will remember. You will need to enter the password when you launch the instance.' There is a text input field labeled 'Name *' containing the text 'my-test-keypair'. At the bottom of the dialog is a large blue button labeled 'Create and Download'. Below the dialog, a portion of the 'Launch instance' form is visible, showing a dropdown menu set to 'Enabled (use subnet setting)'.

The key pair automatically downloads to a location on your computer, typically in the *Downloads* folder.

- c) The **Create key pair** dialog will close, and the **Key name** text box will be populated with the name of the key pair you just created:

Eucalyptus

Launch new instance

1 Image
2 Details
3 Security
4 Advanced

Specify VPC settings, key pair and security group.

VPC network  vpc-aa946ef6

VPC subnet 172.31.0.0/20 (subnet-2def5c71) | one

Auto-assign public IP  Enabled (use subnet setting)

Key name * my-key-pair

Or: [Create key pair](#)

Security group * Select...

Or: [Create security group](#)

Specify an IAM role if you would like to give this instance special access privileges.

Role Select...

- On the Create security group dialog, type the name of your security group into the **Name** text box.
- Type a brief description of your security group into the **Description** text box.
- We'll need to SSH into our instance later, so in the **Rules** section of the dialog, select the SSH protocol from the **Protocol** drop-down list box.
- Note:** In this example, we allow any IP address to access our new instance. For production use, please use appropriate caution when specifying an IP range. For more information on CIDR notation, go to [CIDR notation](#).

You need to specify an IP address or a range of IP addresses that can use SSH to access your instance. For this example, click the **Open to all addresses** link. This will populate the **IP Address** text box with 0.0.0.0/0, which allows any IP address to access your instance via SSH.

Create security group

Name * my-test-security-group

Description * This is my test security group.

VPC Network vpc-aa946ef6

Rules

Inbound

Outbound

Add an inbound rule:

Protocol SSH (TCP port 22, for terminal access)

Port range 22 - 22

Allow traffic from ☒ IP address

0.0.0.0/0

[Open to all addresses](#)

[Use my IP address](#)

☐ Security group

select...

Add Rule

Cancel

Create Security Group

- i) Click the **Add rule** button. The **Create security group** dialog should now look something like this:

Create security group

Name * my-test-security-group

Description * This is my test security group.

VPC Network vpc-aa946ef6

Rules

Inbound Outbound

TCP (22) 0.0.0.0/0 ✕

Add another inbound rule:

Protocol select...

Create Security Group

- j) Click the **Create security group** button.

The **Create security group** dialog will close, and the **Security group** text box will be populated with the name of the security group you just created:

Eucalyptus

[Home](#) / [Instances](#) / Launch instance

Launch new instance

1 Image

Key name [my-key-pair](#)

Security group(s) [my-test-security-group](#)

Launch time 04:55:11 PM Sep 18 2015

Account ID 000143084910

Reservation ID r-2df38753

User data 

- Using the public IP address or hostname of your new instance, you can now use SSH to log into the instance using the private key file you saved when you created a key pair. For example:

```
ssh -i my-test-keypair.private root@10.111.57.109
```

Set Up A Web Server on an Instance

Once you've launched an instance and connected to it, you can test it by setting up a web server.

- ssh into your instance.

```
ssh 192.168.1.1 -l root
```

- Install Apache:

```
yum install -y httpd
```

You should see output similar to the following:

```
Loaded plugins: fastestmirror, security, versionlock
Loading mirror speeds from cached hostfile
* extras: centos.sonn.com
Midokura-local | 2.9 kB | 00:00
centos-7-x86_64-os | 3.7 kB | 00:00
centos-7-x86_64-updates | 3.4 kB | 00:00
centos-7-x86_64-updates/primary_db | 5.4 MB | 00:00
epel-7-x86_64 | 4.4 kB | 00:00
epel-7-x86_64/primary_db | 6.3 MB | 00:00
euca2ools-release | 1.2 kB | 00:00
eucalyptus-release | 1.3 kB | 00:00
eucalyptus-release/primary | 417 kB | 00:00
extras | 3.3 kB | 00:00
Setting up Install Process
Package httpd-2.2.15-31.el7.centos.x86_64 already installed and latest
version
Nothing to do
```

- Start the web server:

```
systemctl start httpd.service
```

You should see output similar to the following:

```
Starting httpd: [ OK ]
```

- Test connectivity to your instance by using a web browser and connecting to the web service on your instance.

For example:

Reboot an Instance with the Management Console

Rebooting preserves the root filesystem of an instance across restarts. To reboot an instance:

1. On the **Instances** page, select **Reboot** from the **Actions** menu next to the instance you want to reboot.

Getting Started with Euca2ools

This section helps you get started using your Eucalyptus cloud, and covers setting up your user credentials, installing and configuring the command line tools, and working with images and instances.

As a cloud user, you can access the Eucalyptus cloud using a command line interface such as Euca2ools, or using a web-based interface such as the Eucalyptus Management Console. You can switch between them freely. What you create in one will be accessible through the other.

Note:

This section primarily deals with using the Eucalyptus command line. For complete documentation on using web-based the Eucalyptus Console, see [Console Login](#).

To access Eucalyptus via the command line tools, you need keys for Euca2ools. To access Eucalyptus with the Management Console, you'll need a password for the Management Console. Talk to your cloud administrator to get your keys and passwords.

Find an Image

To find an image:

1. Enter the following command:

```
euca-describe-images
```

The output displays all available images.

```
IMAGE emi-EC1410C1 centos-32/centos.5-3.x86.img.manifest.xml #
admin available public x86_64 machine
IMAGE eki-822C1344 kernel-i386/vmlinuz-2.6.28-11-server.manifest.xml #
admin available public x86_64 kernel
IMAGE eri-A98C13E4 initrd-64/initrd.img-2.6.28-11-generic.manifest.xml #
admin available public x86_64 ramdisk
```

2. Look for the image ID in the second column and write it down. The image ID starts with `emi-`.

Once you find a suitable image to use, make sure you have a keypair to use.

Create Key Pairs

Eucalyptus uses cryptographic key pairs to verify access to instances. Key pairs are used if you want to connect to your instance using SSH. Creating a key pair generates two keys: a public key (saved within Eucalyptus) and a corresponding private key (output to the user as a character string). To enable this private key you must save it to a file and set appropriate access permissions (using the `chmod` command), as shown in the example below.

Create Key Pairs with the Console

1. From the main dashboard screen, click the **Key Pairs** icon.

The **Key Pairs** page opens.

2. Click the **Create Key Pair** button.

The **Create new key pair** window opens.

3. Type a name for the new key pair into the **Name** text box.

The name may contain up to 255 alphanumeric and special characters.

4. Click the **Create and Download** button. The private half of the key pair (.pem file) is saved to the default download location for your browser.

Note: Keep your private key file in a safe place. If you lose it, you will be unable to access instances created with the key pair.

5. Change file permissions to enable access to the private key file in the local directory. For example, on a Linux or Mac OS X system:

```
chmod 0600 <keypair_name>.private
```

Create Key Pairs with the Command Line

1. Enter the following command:

```
euca-create-keypair <keypair_name> -f <keypair_name>.private
```

where `<keypair_name>` is a unique name for your keypair. For example:

```
euca-create-keypair alice-keypair -f alice-keypair.private
```

The private key is saved to a file in your local directory.

2. Query the system to view the public key:

```
euca-describe-keypairs
```

The command returns output similar to the following:

```
KEYPAIR alice-keypair
ad:0d:fc:6a:00:a7:e7:b2:bc:67:8e:31:12:22:c1:8a:77:8c:f9:c4
```

Authorize Security Groups

Before you can log in to an instance, you must authorize access to that instance. This done by configuring a security group for that instance.

A security group is a set of networking rules applied to instances associated with a group. When you first create an instance, it is assigned to a default security group that denies incoming network traffic from all sources. To allow login and usage of a new instance, you must authorize network access to the default security group with the `euca-authorize` command.

To authorize a security group, use `euca-authorize` with the name of the security group, and the options of the network rules you want to apply.

```
euca-authorize <security_group>
```

Use the following command to grant unlimited network access using SSH (TCP, port 22) and VNC (TCP, ports 5900 to 5910) to the security group `default`:

```
euca-authorize -P tcp -p 22 -s 0.0.0.0/0 default
euca-authorize -P tcp -p 5900-5910 -s 0.0.0.0/0 default
```

Use the following command to grant unlimited network access using Windows Remote Desktop (TCP, port 3389) to the security group `windows`:

```
euca-authorize -P tcp -p 3389 -s 0.0.0.0/0 windows
```

Launch an Instance

To launch an instance:

1. Use the `euca-run-instances` command and provide an image ID and the user data file, in the format `euca-run-instances <image_id>`. For example:

```
euca-run-instances emi-EC1410C1
```

For additional details and options that can be used with the `euca-run-instances` command, For more information, see [EC2-Compatible Commands](#), `euca-run-instances`.

2. Enter the following command to get the launch status of the instance:

```
euca-describe-instances <instance_id>
```

Log in to an Instance

For a Linux Instance

When you create an instance, Eucalyptus assigns the instance two IP addresses: a public IP address and a private IP address. The public IP address provides access to the instance from external network sources; the private IP address provides access to the instance from within the Eucalyptus cloud environment. Note that the two IP addresses may be the same depending on the current networking mode set by the administrator. For more information on Eucalyptus networking modes, see the Eucalyptus Administrator's Guide.

To use an instance you must log into it via `ssh` using one of the IP addresses assigned to it. You can obtain the instance's IP addresses using the `euca-describe-instances` query as shown in the following example.

To log into a VM instance:

1. Enter the following command to view the IP addresses of your instance:

```
euca-describe-instances
```

Eucalyptus returns output similar to the following:

```
RESERVATION r-338206B5 alice default
INSTANCE i-4DCF092C emi-EC1410C1 192.168.7.24 10.17.0.130 # running
alice-keypair 0 m1.small 2010-03-15T21:57:45.134Z
```

Note that the public IP address appears after the image name, with the private address immediately following.

2. Look for the instance ID in the second field and write it down. Use this ID to manipulate and terminate this instance.
3. **Note:** Be sure that the security group for the instance allows SSH access. For more information, see [Authorize Security Groups](#).

Use SSH to log into the instance, using your private key and the external IP address. For example:

```
ssh -i alice-keypair.private root@192.168.7.24
```

You are now logged in to your Linux instance.

Using SSH to Connect via PuTTY

If you are a Windows user and want to securely connect to instances via PuTTY, you must first have a key pair.

1. If you don't have a key pair, you can create one through the Management Console or the command line. See [Create Key Pairs](#).
2. For the key pair to be used with PuTTY, convert your .pem file to a .ppk file by performing the last step in the [Creating SSH Credentials for the Master Node: Modify Your PEM File](#) procedure.

For a Windows Instance:

Log into Windows VM instances using a Remote Desktop Protocol (RDP) client. An RDP prompts you for a login name and password. By default, Windows VM instances are configured with a single user (named Administrator) and a random password generated at boot time. So, before you can log into a Windows VM instance via RDP, you must retrieve the random password generated at boot time using the `euca-get-password` command.

To log into a Windows instance:

1. Use `euca-describe-groups` to make sure the port for remote desktop (3389) is authorized in your security group.

The response from this command will look like the following example.

```
GROUP 955340183797 default default group
PERMISSION 955340183797 default ALLows tcp 3389 3389 FROM CIDR 0.0.0.0/0
```

2. Enter the `euca-get-password` command followed by the unique id tag of the Windows VM instance and the `-k` option with the name of private key file that corresponds to your credential keypair. In the following example we retrieve the password for a Windows VM instance with id tag `i-5176095D` and private key file name `mykey.private`.

```
euca-get-password i-5176095D -k mykey.private
```

3. Log into the RDP client using the public (external) IP address associated with the running Windows VM instance. Enter the following command to view the IP addresses of your instance:

```
euca-describe-instances
```

4. At the **Log On to Windows** prompt, prepend the user name **Administrator** to the public IP address of the instance, and enter the password that you retrieved with `euca-get-password`, as shown:

You are now logged in and ready to use your Windows instance.

Set Up A Web Server on an Instance

Once you've launched an instance and connected to it, you can test it by setting up a web server.

1. ssh into your instance.

```
ssh 192.168.1.1 -l root
```

2. Install Apache:

```
yum install -y httpd
```

You should see output similar to the following:

```
Loaded plugins: fastestmirror, security, versionlock
Loading mirror speeds from cached hostfile
* extras: centos.sonn.com
Midokura-local | 2.9 kB | 00:00
centos-7-x86_64-os | 3.7 kB | 00:00
centos-7-x86_64-updates | 3.4 kB | 00:00
centos-7-x86_64-updates/primary_db | 5.4 MB | 00:00
epel-7-x86_64 | 4.4 kB | 00:00
epel-7-x86_64/primary_db | 6.3 MB | 00:00
euca2ools-release | 1.2 kB | 00:00
eucalyptus-release | 1.3 kB | 00:00

extras | 3.3 kB | 00:00
Setting up Install Process
Package httpd-2.2.15-31.el7.centos.x86_64 already installed and latest
version
Nothing to do
```

3. Start the web server:

```
systemctl start httpd.service
```

You should see output similar to the following:

```
Starting httpd: [ OK ]
```

4. Test connectivity to your instance by using a web browser and connecting to the web service on your instance.

For example:

Reboot an Instance

Rebooting preserves the root filesystem of an instance across restarts. To reboot an instance:

Enter the following command:

```
euca-reboot-instances <instance_id>
```

To reboot the instance `i-34523332`, enter:

```
euca-reboot-instances i-34523332
```

Terminate an Instance

The `euca-terminate-instances` command lets you cancel running VM instances. When you terminate instances, you must specify the ID string of the instance(s) you wish to terminate. You can obtain the ID strings of your instances using the `euca-describe-instances` command.

Warning: Terminating an instance can cause the instance and all items associated with the instance (data, packages installed, etc.) to be lost. Be sure to save any important work or data to Walrus or EBS before terminating an instance.

To terminate VM instances:

1. Enter `euca-describe-instances` to obtain the ID of the instances you wish to terminate. Note that an instance ID strings begin with the prefix `i-` followed by an 8-character string:

```
euca-describe-instances
RESERVATION r-338206B5 alice default
INSTANCE i-4DCF092C emi-EC1410C1 192.168.7.24 10.17.0.130 #
running mykey 0 m1.small 2010-03-15T21:57:45.134Z #
wind eki-822C1344 eri-BFA91429
```

2. Enter `euca-terminate-instances` and the ID string(s) of the instance(s) you wish to terminate:

```
euca-terminate-instances i-4DCF092C
INSTANCE i-3ED007C8
```

Using Instances

Any application that runs on a cloud, whether public or private or hybrid, runs inside at least one *instance*. To start using the cloud, you must launch one or more instances. Every instance is created from stored *images*. An image contains the basic operating system and often other software that will be needed when the instance is running. When you launch an instance, you tell the cloud what image to base the instance on. Your cloud administrator should have set up a catalog of standard or customized images for you to use.

To find out more about what instances are, see [Instance Overview](#).

To find out how to use CloudWatch, see [Instance Tasks](#).

Instance Overview

An instance is a virtual machine (VM). Eucalyptus allows you to run instances from both Linux-based and Windows-based images.

The following sections describe instances in more detail.

Instance Concepts

This section describes conceptual information to help you understand instances.

Eucalyptus Machine Image (EMI)

A Eucalyptus machine image (EMI) is a copy of a virtual machine bootable file system stored in the Walrus storage. An EMI is a template from you can use to deploy multiple identical instances—or copies of the virtual machine.

EMIs are analogous to Amazon Machine Images (AMIs) in AWS. In fact, you can download and deploy any of the 10,000+ AMIs as EMIs in a Eucalyptus cloud without significant modification. While it is possible to build your own EMI, it might be just as simple to find a thoroughly vetted, freely available image in AWS, download it to your Eucalyptus cloud, and use that instead.

EMIs can be Linux or Windows-based. In Linux it is an image of the / file system while in Windows it is an image of the C: drive.

When registered in a Eucalyptus cloud, each distinct EMI is given a unique ID for identification. The ID is in the format `emi-<nnnnnnnn>`.

Instance

A instance is a virtual machine deployed from an EMI. An instance then, is simply a running copy of an EMI, which means it always starts from a known baseline. There are two types of instances; instance store-backed and EBS-backed. This section describes store-backed instances. For information about EBS-backed instances, see [Using EBS](#).

Every instance receives a unique ID in the format `i-<nnnnnnnn>`.

You can deploy multiple instances using a single command. In this case all the instances will have unique instance IDs but will share a common reservation ID. This reservation ID can be seen, for example, from the `euca2ools euca-describe-instances` command that lists running instances. Reservations IDs appear in the format `r-<nnnnnnnn>`.

Tip: A *reservation* is an EC2 term used to describe the resources reserved for one or more instances launched in the cloud.

Persistence

Applications running in ephemeral instances that generate data that must be saved should write that data to some place other than the instance itself. There are two Eucalyptus options available. First, the data can be written to a volume that is attached to the instance. Volumes provided by the Storage Controller and attached to instances are persistent. Second, the data could be written to the Walrus using HTTP put/get operations. Walrus storage is also persistent.

If the application cannot be rewritten to send data to a volume or the Walrus, then the application should be deployed inside an EBS-backed instance. EBS-backed instances are persistent and operate in a manner more similar to a physical machine.

Instance Basics

This section describes information to help you decide which type of instance you need.

Virtual Machine Types

A virtual machine type, known as a VM type, defines the number of CPUs, the size of memory, and the size of storage that is given to an instance when it boots. There are five pre-defined VM types in Eucalyptus. You can change the quantity of resources associated with each of the five VM types, but you cannot change the name of the VM types or the number of VM types available. If you customize the sizes they must be well-ordered. That means that the CPU, memory, and storage sizes of the next VM type must be equal to, or larger than, the size of the preceding VM type.

The VM type used to instantiate an EMI must have a defined disk size larger than the EMI file. If a 6GB EMI is loaded into an instance with a VM type defined with a 5GB disk, it will fail to boot. The status of the instance will show as *pending*. The pending status is the result of the fact that the Walrus cannot finish downloading the image to the Node Controller because the Node Controller has not allotted sufficient disk space for the download. Starting with Eucalyptus 3.2, if the user attempts to launch an instance with a VM type that is too small, they will receive an on-screen warning and the operation will terminate.

Available VM Types

Eucalyptus, like AWS, offers families of VM types. These families are composed of varying combinations of CPU, disk size, and memory. Eucalyptus offers enough VM types to give you the flexibility to choose the appropriate mix of resources for your applications. For the best experience, we recommend that you launch instance types that are appropriate for your applications.

- **General Purpose:** This family includes the M1 and M3 VM types. These types provide a balance of CPU, memory, and network resources, which makes them a good choice for many applications. The VM types in this family range in size from one virtual CPU with two GB of RAM to eight virtual CPUs with 30 GB of RAM. The balance of resources makes them ideal for running small and mid-size databases, more memory-hungry data processing tasks, caching fleets, and backend servers.

M1 types offer smaller instance sizes with moderate CPU performance. M3 types offer larger number of virtual CPUs that provide higher performance. We recommend you use M3 instances if you need general-purpose instances with demanding CPU requirements.

- **Compute Optimized:** This family includes the C1 and CC2 instance types, and is geared towards applications that benefit from high compute power. Compute-optimized VM types have a higher ratio of virtual CPUs to memory than other families but share the NCs with non optimized ones. We recommend this type if you are running any CPU-bound scale-out applications. CC2 instances provide high core count (32 virtual CPUs) and support for cluster networking. C1 instances are available in smaller sizes and are ideal for scaled-out applications at massive scale.
- **Memory Optimized:** This family includes the CR1 and M2 VM types and is designed for memory-intensive applications. We recommend these VM types for performance-sensitive database, where your application is memory-bound. CR1 VM types provide more memory and faster CPU than do M2 types. CR1 instances also support cluster networking for bandwidth intensive applications. M2 types are available in smaller sizes, and are an excellent option for many memory-bound applications.
- **Micro:** This Micro family contains the T1 VM type. The t1.micro provides a small amount of consistent CPU resources and allows you to increase CPU capacity in short bursts when additional cycles are available. We recommend this type for lower throughput applications like a proxy server or administrative applications, or for low-traffic websites that occasionally require additional compute cycles. We do not recommend this VM type for applications that require sustained CPU performance.

The following tables list each VM type Eucalyptus offers. Each type is listed in its associate VM family.

Table 1: General Purpose VM Types

Instance Type	Virtual CPU	Disk Size	Memory
m1.small	1	5	256
m1.medium	1	10	512
m1.large	2	10	512

Instance Type	Virtual CPU	Disk Size	Memory
m1.xlarge	2	10	1024
m3.xlarge	4	15	2048
m3.2xlarge	4	30	4096

Table 2: Compute Optimized VM Types

Instance Type	Virtual Cores	Disk Size	Memory
c1.medium	2	10	512
c1.xlarge	2	10	2048
cc1.4xlarge	8	60	3072
cc2.8xlarge	16	120	6144

Table 3: Memory Optimized VM Types

Instance Type	Virtual Cores	Disk Size	Memory
m2.xlarge	2	10	2048
m2.2xlarge	2	30	4096
m2.4xlarge	8	60	4096
cr1.8xlarge	16	240	16384

Table 4: Micro VM Types

Instance Type	Virtual Cores	Disk Size	Memory
t1.micro	1	5	256

Linux and Windows Instances

A Linux instance store-backed instance actually consists of three separate images:

- The Linux boot disk image (EMI) as previously defined
- A Eucalyptus kernel image (EKI), which is a low level operating system component that interfaces with the instance's virtual hardware
- A Eucalyptus ramdisk image (ERI) - the initrd - which is the initial root file system that is loaded as part of the kernel boot procedure and loads modules that make it possible to access the real root file system in the second stage of the boot process

When a Linux instance is launched, these three images (along with a few other files) are bound together using loop devices so that they appear as a single disk to the Linux operating system running in the instance. For Linux images, the same kernel and ramdisk files can be shared across multiple boot disk images, which allows for more efficient use of storage.

A Windows instance store-backed instance consists only of the bootable file system image (EMI). The reason for this is that in the Windows operating system the kernel and ramdisk components cannot be separated from the boot disk image, and thus each copy of a Windows image must also contain a copy of these components.

Ephemeral Linux Instances

Instance store-backed instances are ephemeral instances. This means that any changes made to a running instance are lost if the instance is either purposely or accidentally terminated. Applications running in ephemeral instances should write their data to persistent storage for safe keeping. Persistent storage available to instances includes Storage Controller volumes and the Walrus.

As an instance store-backed instance is launched, several files are brought together using loop devices on the Node Controller. As these files are brought together they form what looks like a disk to the instance's operating system. The illustration below lists a some of the files that make up a running instance. Notice that the EKI, EMI, and ERI images are presented to the instance's operating system as the partition `/dev/sda1` and are mounted as the `/` file system.

```
# ls /var/lib/eucalyptus/instances/work/NKGEED1B2WWI5HNBNTA6/i-364F3EA5
-rw-rw-r-- 1 eucalyptus eucalyptus 2231705 Feb 10 12:59 eki-456E3AD5-67c370b8.blocks
-rw-r----- 1 eucalyptus eucalyptus 1049624576 Feb 10 12:59 emi-FF113B5A-4f6788c4.blocks
-rw-rw-r-- 1 eucalyptus eucalyptus 6260769 Feb 10 12:59 eri-A2BA3BE6-d06764a6.blocks
-rw-r----- 1 eucalyptus eucalyptus 536870912 Feb 10 12:59 prt-00512swap-ac8d5670.blocks
-rw-r----- 1 eucalyptus eucalyptus 560988160 Feb 10 12:59 prt-00535ext3-43e32609.blocks
```

2GB storage VMtype

/dev/sda1
/dev/sda2
/dev/sda3

Assume that the illustration above shows some of the files that make up an instance that was launched in a vmtype with 2GB of storage. Notice that the `eki-*`, `emi-*`, and `eri-*` files have been downloaded from the Walrus and cached on the Node Controller. These three files consume around 1.06GB of storage space. Notice also that a swap file was automatically created for the instance. The swap file has the string `swap` in its name and the file is approximately 500MB in size. It is presented to the instance's operating system as the partition `/dev/sda3`.

This means the EKI, ERI, EMI, and swap files have consumed approximately 1.5GB of the available 2GB of storage space. The remaining 500GB is allocated to the file with the string `ext3` in its name. In our example, this space is formatted as an ext3 file system and is made available to the instance as the disk partition `/dev/sda2`, and is actually mounted to the `/mnt` directory in the instance. An example of this configuration is shown below.

Ephemeral Windows Instances

It is also possible to launch ephemeral Windows instances. Just like their Linux counterparts, modifications to Windows instance store-backed instances are lost when instances are purposely or accidentally terminated.

Ephemeral space in a Windows instance store-backed instance is presented as formatted drive space accessible via a logical drive letter. The logical drive is sized so that the instance's total storage size matches the vmtype's storage size.

Windows Instance Support

Eucalyptus supports several different Windows operating system versions running as instances. Normal Windows licensing policies still apply. See the [Compatibility Matrix](#) in the [Release Notes](#) for supported versions.

A VNC client is required during initial installation of the operating system but once Windows is fully installed, Remote Desktop Protocol can be used to connect to the Windows desktop. The VNC client is unnecessary if the Windows installation is configured as an unattended installation. As an example of one way to set up a Windows 7 unattended installation, see <http://www.intowindows.com/how-to-create-unattended-windows-7-installation-setup>.

All Windows images should be created on the hypervisor that runs on the Node Controllers. Eucalyptus does not support running a Windows image across multiple hypervisors. The Eucalyptus Windows Integration software, installed in the Windows EMI, has a utility that adds permissions to users or groups that allows them to use RDP to access the Windows desktop. By default, only the Administrator can do this. The Eucalyptus Windows Integration software also installs the Virtio device drivers for disk and network into the EMI so that it can run on a host configured with a KVM hypervisor. For more information about how to create a Windows image and install the Eucalyptus Windows Integration software, see the *Eucalyptus User Guide*.

EBS-Backed Instances

Eucalyptus supports two different types of instances; instance store-backed instances and EBS-backed instances. This section describes EBS-backed instances.

With EBS-backed instances you are booting an instance from a volume rather than a bundled EMI image. The boot volume is created from a snapshot of a root device volume. EBS-backed instances can be either Linux or Windows. The boot volume is persistent so changes to the instance are persistent.

Note: Linux boot-from-EBS instances do not require EKI and ERI images like instance store-backed instances.

Comparing Instance Types

The graphic below illustrates the differences between an instance store-backed instance and an EBS-backed instance.

Both types of instances still boot from an EMI; the difference is what is behind the EMI. For an instance store-backed instance the EMI is backed by a bundled image. For an EBS-backed instance the EMI is backed by a snapshot of a volume that contains bootable software, similar to a physical host's boot disk.

Note that for the instance store-backed instance, the EMI, EKI, and ERI (assuming Linux) are copied from the Walrus directly to Node Controller. Both disk and memory on the Node Controller are used as cache so an instance store-backed instance can be considered a cache-based instance and is not persistent. Once the instance is terminated both the RAM and the disk cache are cleared and any modifications to the instance are lost.

When an EBS-backed instance is launched, the snapshot on which the EMI is based is automatically copied to a new volume which is then attached to the instance. The instance then boots from the attached volume. Changes to the EBS-backed instance are persistent because the volume used to boot the EBS-backed instance is persistent. As a result, EBS-backed instances can be suspended and resumed and not just terminated like an instance store-backed instance.

Using EBS-Backed Instances

An EBS-backed instance is very much like a physical machine in the way it boots and persists data. Because an EBS-backed instance functions in a manner similar to physical machine, it makes it a good choice to run legacy applications that cannot be re-architected for the cloud.

EBS-backed instances provide a workaround for the 10GB size limit for instance store-backed EMI images. This is particularly important for Windows instances which can easily exceed 10GB in size. EBS-backed instances have a maximum size of 1TB.

An EBS-backed boot volume can still be protected by taking a snapshot of it. In fact, other non-boot volumes can be attached to the EBS-backed instance and they can be protected using snapshots too.

Suspending and Resuming EBS-Backed Instances

An EBS-backed instance can be suspended and resumed, similar to the operating system and applications on a laptop. The current state of the EBS-backed instance is saved in a suspend operation and restored in a resume operation. Like instance store-backed instances, an EBS-backed instance can also be rebooted and terminated.

To suspend a running EBS-backed instance:

```
euca-stop-instances i-<nnnnnnnn>
```

To resume a suspended EBS-backed instance:

```
euca-start-instances i-<nnnnnnnn>
```

To reboot an EBS-backed instance:

```
euca-reboot-instances i-<nnnnnnnn>
```

To terminate an EBS-backed instance:

```
euca-terminate-instances i-<nnnnnnnn>
```

EBS EMI Creation Overview

You can create an EBS EMI from an existing `.img` file or create your own `.img` file. One way to create your own EBS `.img` file is to use `virt-install` as described below.

Use `virt-install` on a system with the same operating system version and hypervisor as your Node Controller. When using `virt-install`, select `scsi` as the disk type for KVM if the VIRTIO paravirtualized devices are not enabled. If you have KVM with VIRTIO enabled (the default), select `virtio` as the disk type of the virtual machine. If you create, successfully boot, and connect the virtual machine to the network in this environment, it should boot as an EBS-backed instance in the Eucalyptus cloud.

Note: For CentOS or RHEL images, you will typically need to edit the `/etc/sysconfig/network-scripts/ifcfg-eth0` file and remove the `HWADDR` line. This is because an instance's network interface will always be assigned a different hardware address at instantiation.

Note: WARNING: If you use an image created by `virt-install` under a different distribution or hypervisor combination, it is likely that it will not install the correct drivers into the ramdisk and the image will not boot on your Node Controller.

To create an EMI for EBS-backed instances will require initial assistance from a *helper* instance. The helper instance can be either an instance store-backed or EBS-backed instance and can be deleted when finished. It only exists to help create the initial volume that will be the source of the snapshot behind the EMI used to boot other EBS-backed instances.

First you will need to create a volume large enough to contain the boot image file that was created by `virt-install`. Once this volume has been created attach it to the helper instance. Then transfer the boot image file to the helper instance. The helper instance must have enough free disk space to temporarily hold the boot image file. Once there, transfer the boot image file, using the `dd` command, to the attached volume.

At this point the volume can be detached from the helper instance, a snapshot taken, and the snapshot registered as a new EMI.

The process to create a new EMI is summarized as follows:

1. Create the `.img` file using `virt-install` (the `.img` file is the virtual machine's disk file).
2. Create the helper instance.
3. Create and attach the volume to the helper instance.
4. Copy the `.img` file to the helper instance and from there to the attached volume.
5. Detach the volume and take a snapshot of it.
6. Register the snapshot as a new EMI.

This process is illustrated below.

Create an EBS EMI

To create a new EMI that is used to boot EBS-backed instances:

1. Create a new volume whose size matches the size of the bootable .img file:

```
euca-create-volume -z <cluster_name> -s <size_GB>
```

2. Attach the volume to a helper instance:

```
euca-attach-volume vol-<nnnnnnnn> -i i-<nnnnnnnn> -d <device>
```

3. Log in to the instance and copy the bootable image from its source to the helper instance.

4. While logged in to the helper instance, copy a bootable image to the attached volume:

```
dd if=/<path_to_image> of=<device> bs=1M
```

5. While logged in to the helper instance, flush the file system buffers after running the dd command:

```
sync
```

6. Detach the volume from the instance:

```
euca-detach-volume vol-<nnnnnnnn>
```

7. Create a snapshot of the bootable volume:

```
euca-create-snapshot vol-<nnnnnnnn>
```

8. Register the bootable volume as a new EMI:

```
euca-register --name "<descriptive_name>" /
--snapshot snap-<nnnnnnnn>
```

9. Run a new EBS-backed instance:

```
euca-run-instances -k <key_name> emi-<nnnnnnnn>
```

Note: The snapshot cannot be deleted unless the EMI is first deregistered.

Instance Tasks

This section describes the tasks you can perform with instances in Eucalyptus.

Find an Image

To find an image:

1. Enter the following command:

```
euca-describe-images
```

The output displays all available images.

```
IMAGE emi-EC1410C1 centos-32/centos.5-3.x86.img.manifest.xml #
admin available public x86_64 machine
IMAGE eki-822C1344 kernel-i386/vmlinuz-2.6.28-11-server.manifest.xml #
admin available public x86_64 kernel
IMAGE eri-A98C13E4 initrd-64/initrd.img-2.6.28-11-generic.manifest.xml #
admin available public x86_64 ramdisk
```

2. Look for the image ID in the second column and write it down. The image ID starts with `emi-`.

Once you find a suitable image to use, make sure you have a keypair to use.

Create Key Pairs

Eucalyptus uses cryptographic key pairs to verify access to instances. Key pairs are used if you want to connect to your instance using SSH. Creating a key pair generates two keys: a public key (saved within Eucalyptus) and a corresponding private key (output to the user as a character string). To enable this private key you must save it to a file and set appropriate access permissions (using the `chmod` command), as shown in the example below.

Create Key Pairs with the Console

1. From the main dashboard screen, click the **Key Pairs** icon.
The **Key Pairs** page opens.
2. Click the **Create Key Pair** button.
The **Create new key pair** window opens.
3. Type a name for the new key pair into the **Name** text box.
The name may contain up to 255 alphanumeric and special characters.
4. Click the **Create and Download** button. The private half of the key pair (.pem file) is saved to the default download location for your browser.

Note: Keep your private key file in a safe place. If you lose it, you will be unable to access instances created with the key pair.
5. Change file permissions to enable access to the private key file in the local directory. For example, on a Linux or Mac OS X system:

```
chmod 0600 <keypair_name>.private
```

Create Key Pairs with the Command Line

1. Enter the following command:

```
euca-create-keypair <keypair_name> -f <keypair_name>.private
```

where `<keypair_name>` is a unique name for your keypair. For example:

```
euca-create-keypair alice-keypair -f alice-keypair.private
```

The private key is saved to a file in your local directory.

2. Query the system to view the public key:

```
euca-describe-keypairs
```

The command returns output similar to the following:

```
KEYPAIR alice-keypair
ad:0d:fc:6a:00:a7:e7:b2:bc:67:8e:31:12:22:c1:8a:77:8c:f9:c4
```

Authorize Security Groups

Before you can log in to an instance, you must authorize access to that instance. This done by configuring a security group for that instance.

A security group is a set of networking rules applied to instances associated with a group. When you first create an instance, it is assigned to a default security group that denies incoming network traffic from all sources. To allow login and usage of a new instance, you must authorize network access to the default security group with the `euca-authorize` command.

To authorize a security group, use `euca-authorize` with the name of the security group, and the options of the network rules you want to apply.

```
euca-authorize <security_group>
```

Use the following command to grant unlimited network access using SSH (TCP, port 22) and VNC (TCP, ports 5900 to 5910) to the security group default:

```
euca-authorize -P tcp -p 22 -s 0.0.0.0/0 default
euca-authorize -P tcp -p 5900-5910 -s 0.0.0.0/0 default
```

Use the following command to grant unlimited network access using Windows Remote Desktop (TCP, port 3389) to the security group windows:

```
euca-authorize -P tcp -p 3389 -s 0.0.0.0/0 windows
```

Launch an Instance

To launch an instance:

1. Use the `euca-run-instances` command and provide an image ID and the user data file, in the format `euca-run-instances <image_id>`. For example:

```
euca-run-instances emi-EC1410C1
```

For additional details and options that can be used with the `euca-run-instances` command, For more information, see [EC2-Compatible Commands, euca-run-instances](#).

2. Enter the following command to get the launch status of the instance:

```
euca-describe-instances <instance_id>
```

Log in to an Instance

For a Linux Instance

When you create an instance, Eucalyptus assigns the instance two IP addresses: a public IP address and a private IP address. The public IP address provides access to the instance from external network sources; the private IP address provides access to the instance from within the Eucalyptus cloud environment. Note that the two IP addresses may be the same depending on the current networking mode set by the administrator. For more information on Eucalyptus networking modes, see the Eucalyptus Administrator's Guide.

To use an instance you must log into it via `ssh` using one of the IP addresses assigned to it. You can obtain the instance's IP addresses using the `euca-describe-instances` query as shown in the following example.

To log into a VM instance:

1. Enter the following command to view the IP addresses of your instance:

```
euca-describe-instances
```

Eucalyptus returns output similar to the following:

```
RESERVATION r-338206B5 alice default
INSTANCE i-4DCF092C emi-EC1410C1 192.168.7.24 10.17.0.130 # running
alice-keypair 0 m1.small 2010-03-15T21:57:45.134Z
```

Note that the public IP address appears after the image name, with the private address immediately following.

2. Look for the instance ID in the second field and write it down. Use this ID to manipulate and terminate this instance.
3. **Note:** Be sure that the security group for the instance allows SSH access. For more information, see [Authorize Security Groups](#).

Use SSH to log into the instance, using your private key and the external IP address. For example:

```
ssh -i alice-keypair.private root@192.168.7.24
```

You are now logged in to your Linux instance.

Using SSH to Connect via PuTTY

If you are a Windows user and want to securely connect to instances via PuTTY, you must first have a key pair.

1. If you don't have a key pair, you can create one through the Management Console or the command line. See [Create Key Pairs](#).
2. For the key pair to be used with PuTTY, convert your .pem file to a .ppk file by performing the last step in the [Creating SSH Credentials for the Master Node: Modify Your PEM File](#) procedure.

For a Windows Instance:

Log into Windows VM instances using a Remote Desktop Protocol (RDP) client. An RDP prompts you for a login name and password. By default, Windows VM instances are configured with a single user (named Administrator) and a random password generated at boot time. So, before you can log into a Windows VM instance via RDP, you must retrieve the random password generated at boot time using the `euca-get-password` command.

To log into a Windows instance:

1. Use `euca-describe-groups` to make sure the port for remote desktop (3389) is authorized in your security group.

The response from this command will look like the following example.

```
GROUP 955340183797 default default group
PERMISSION 955340183797 default ALLows tcp 3389 3389 FROM CIDR 0.0.0.0/0
```

2. Enter the `euca-get-password` command followed by the unique id tag of the Windows VM instance and the `-k` option with the name of private key file that corresponds to your credential keypair. In the following example we retrieve the password for a Windows VM instance with id tag `i-5176095D` and private key file name `mykey.private`.

```
euca-get-password i-5176095D -k mykey.private
```

3. Log into the RDP client using the public (external) IP address associated with the running Windows VM instance. Enter the following command to view the IP addresses of your instance:

```
euca-describe-instances
```

4. At the **Log On to Windows** prompt, prepend the user name **Administrator** to the public IP address of the instance, and enter the password that you retrieved with `euca-get-password`, as shown:

You are now logged in and ready to use your Windows instance.

Reboot an Instance

Rebooting preserves the root filesystem of an instance across restarts. To reboot an instance:

Enter the following command:

```
euca-reboot-instances <instance_id>
```

To reboot the instance `i-34523332`, enter:

```
euca-reboot-instances i-34523332
```

Terminate an Instance

The `euca-terminate-instances` command lets you cancel running VM instances. When you terminate instances, you must specify the ID string of the instance(s) you wish to terminate. You can obtain the ID strings of your instances using the `euca-describe-instances` command.

Warning: Terminating an instance can cause the instance and all items associated with the instance (data, packages installed, etc.) to be lost. Be sure to save any important work or data to Walrus or EBS before terminating an instance.

To terminate VM instances:

1. Enter `euca-describe-instances` to obtain the ID of the instances you wish to terminate. Note that an instance ID strings begin with the prefix `i-` followed by an 8-character string:

```
euca-describe-instances
RESERVATION r-338206B5 alice default
INSTANCE i-4DCF092C emi-EC1410C1 192.168.7.24 10.17.0.130 #
running mykey 0 m1.small 2010-03-15T21:57:45.134Z #
wind eki-822C1344 eri-BFA91429
```

2. Enter `euca-terminate-instances` and the ID string(s) of the instance(s) you wish to terminate:

```
euca-terminate-instances i-4DCF092C
INSTANCE i-3ED007C8
```

Using EBS

This section details what you need to know about Eucalyptus Elastic Block Storage (EBS).

EBS Overview

Eucalyptus Elastic Block Storage (EBS) provides block-level storage volumes that you can attach to instances running in your Eucalyptus cloud. An EBS volume looks like any other block-level storage device when attached to a running Eucalyptus instance, and may be formatted with an appropriate file system and used as you would a regular storage device. Any changes that you make to an attached EBS volume will persist after the instance is terminated.

You can create an EBS volume by using the Eucalyptus command line tools or by using the Eucalyptus management console and specifying the desired size (up to 10GB) and availability zone. Once you've created an EBS volume, you can attach it to any instance running in the same availability zone. An EBS volume can only be attached to one running instance at a time, but you can attach multiple EBS volumes to a running instance.

You can create a backup — called a *snapshot* — of any Eucalyptus EBS volume. You can create a snapshot by using the command-line tools or the Eucalyptus management console and simply specifying the volume from which you want to create the snapshot, along with a description of the snapshot. Snapshots can be used to create new volumes.

EBS Tasks

This section contains examples of the most common Eucalyptus EBS tasks.

Create and Attach an EBS Volume

The following example shows how to create a 10 gigabyte EBS volume and attach it to a running instance called `i-000000000` running in availability zone `zone1`.

1. Create a new EBS volume in the same availability zone as the running instance.

```
euca-create-volume --availability-zone zone1 --size 10
```

The command displays the ID of the newly-created volume.

2. Attach the newly-created volume to the instance, specifying the local device name `/dev/sdf`.

```
euca-attach-volume vol-000000000 -i i-000000000 -d /dev/sdf
```

You've created a new EBS volume and attached it to a running instance. You can now access the EBS volume from your running instance.

List Available EBS Volumes

You can use the Eucalyptus command line tools to list all available volumes and retrieve information about a specific volume.

1. To get a list of all available volumes in your Eucalyptus cloud, enter the following command:

```
euca-describe-volumes
```

2. To get information about one specific volume, use the `euca-describe-volumes` command and specify the volume ID.

```
euca-describe-volumes vol-000000000
```

Detach an EBS Volume

To detach a block volume from an instance:

Enter the following command:

```
euca-detach-volume <volume_id>
```

```
euca-detach-volume vol-000000000
```

Create a Snapshot

The following example shows how to create a snapshot.

Enter the following command:

```
euca-create-snapshot <volume_id>
```

```
euca-create-snapshot vol-000000000
```

List Available Snapshots

You can use the Eucalyptus command line tools to list available snapshots and retrieve information about a specific snapshot.

1. To get a list of all available snapshots in your Eucalyptus cloud, enter the following command:

```
euca-describe-snapshots
```

2. To get information about one specific snapshot, use the `euca-describe-snapshots` command and specify the snapshot ID.

```
euca-describe-snapshots snap-000000000
```

Delete a Snapshot

The following example shows how to delete a snapshot.

Enter the following command:

```
euca-delete-snapshot <snapshot_id>
```

```
euca-delete-snapshot mytestsnaphot
```

Using Tags and Filters

This section describes features and tasks that enable you to manage your cloud resources, such as EMIs, instances, EBS volumes, and snapshots.

Tagging and Filtering Overview

This section describes what tagging is, its restrictions, and how tagging relates to filtering.

Tagging Resources

To help you manage your cloud's instances, images, and other Eucalyptus resources, you can assign your own metadata to each resource in the form of tags. You can use tags to create user-friendly names, make resource searching easier, and improve coordination between multiple users. This section describes tags and how to create them.

Tagging Overview

A tag consists of a key and an optional value for that key. You define both the key and the value for each tag. For example, you can define a tag for your instances that helps you track each instance's owner and stack level.

Tags let you categorize your cloud resources in various ways. For example, you can tag resources based on their purpose, their owner, or their environment. We recommend that you devise a set of tag keys that meets your needs for each resource type. Using a consistent set of tag keys makes it easier for you to manage your resources. You can search and filter the resources based on the tags you add. For more information about filtering, see [Filtering Resources](#).

Eucalyptus doesn't apply any semantic meaning to your tags. Instead, Eucalyptus interprets your tags simply as strings of characters. Eucalyptus doesn't automatically assign any tags on resources.

You can only assign tags to resources that already exist. However, if you use the Management Console, you can add tags when you launch an instance. If you add a tag that has the same key as an existing tag on that resource, the new value overwrites the old value. You can edit tag keys and values, and you can remove tags from a resource at any time. You can set a tag's value to the empty string, but you can't set a tag's value to null.

Tagging Restrictions

The following restrictions apply to tags:

Restriction	Description
Maximum number of tags per resource	10
Maximum key length	128 Unicode characters
Maximum value length	256 Unicode characters
Unavailable prefixes	You can't use either <code>euca :</code> or <code>aws :</code> as a prefix to either a tag name or value. These are reserved by Eucalyptus.
Case sensitivity	Tag keys and values are case sensitive.

You can't terminate, stop, or delete a resource based solely on its tags. You must specify the resource identifier. For example, to delete snapshots that you tagged with a tag key called `temporary`, you must first get a list of those snapshots using `euca-describe-snapshots` with a filter that specifies the tag. Then you use `euca-delete-snapshot` with the IDs of the snapshots (for example, `snap-1A2B3C4D`). You can't call `euca-delete-`

snapshots with a filter that specified the tag. For more information about using filters when listing your resources, see [Filtering Resources](#).

Available Resources

You can tag the following cloud resources:

- Images (EMIs, kernels, RAM disks)
- Instances
- Volumes
- Snapshots
- Security Groups

You can't tag the following cloud resources:

- Elastic IP addresses
- Key pairs
- Placement groups

You can tag public or shared resources, but the tags you assign are available only to your account and not to the other accounts sharing the resource.

Filtering Resources

You can search and filter resources based on the tags you use. For example, you can list a Eucalyptus Machine Image (EMI) using `euca-describe-images`, and you can list instances using `euca-describe-instances`.

Filtering Overview

Results from describe commands can be long. Use a filter to include only the resources that match certain criteria. For example, you can filter so that a returned list shows only the 64-bit Windows EMIs that use an EBS volume as the root device volumes.

Filtering also allows you to:

- Specify multiple filter values: For example, you can list all the instances whose type is either `m1.small` or `m1.large`.
- Specify multiple filters: for example, you can list all the instances whose type is either `m1.small` or `m1.large`, and that have an attached EBS volume that is set to delete when the instance terminates.
- Use wildcards with values: For example, you can use `*production*` as a filter value to get all EBS snapshots that include `production` in the description.

In each case, the instance must match all your filters to be included in the results. Filter values are case sensitive. We support only exact string matching, or substring matching (with wildcards).

Tagging and Filtering Tasks

This section details the tasks that you can with tagging and filtering. You can use the Management Console or the command line interface.

Eucalyptus supports three commands for tagging:

- `euca-create-tags`
- `euca-describe-tags`
- `euca-delete-tags`

Eucalyptus supports the following commands for filtering:

- euca-describe-addresses
- euca-describe-availability-zones
- euca-describe-bundle-tasks
- euca-describe-groups
- euca-describe-images
- euca-describe-instances
- euca-describe-keypairs
- euca-describe-regions
- euca-describe-snapshots
- euca-describe-tags
- euca-describe-volumes

For detailed information about these commands, see the [Euca2ools Reference Guide](#).

Add a Tag

Use the `euca-create-tags` command to add a tag to a resource.

Enter the following command and parameters:

```
euca-create-tags [resource_id] --tag [tag_key]=[tag_value]
```

Eucalyptus returns a the resource identifier and its tag key and value.

The following example shows how to add a tag to an EMI. This tag key is `dataserver` and has no value.

```
euca-create-tags emi-1A2B3C4D --tag dataserver
TAG emi-1a2b3c4d image dataserver
```

The following example shows how to add the same two tags to both an EMI and an instance. One tag key is `dataserver`, which has no value, an empty string. The other tag key is `stack`, which has a value of `Production`.

```
euca-create-tags emi-1A2B3C4D i-6F5D4E3A --tag dataserver --tag
stack=Production
TAG emi-1A2B3C4D image dataserver
TAG emi-1A2B3C4D image stack Production
TAG i-6F5D4E3A image dataserver
TAG i-6F5D4E3A image stack Production
```

List Tags

Use the `euca-describe-tags` command to list your tags and filter the results different ways.

Enter the following command and parameters:

```
euca-describe-tags --filter resource-type=[resource_type]" --filter
"key=[key_name]" --filter "value=[key_value]"
```

The following example describes all the tags belonging to your account.

```
euca-describe-tags
TAG emi-1A2B3C4D image database_server
TAG emi-1A2B3C4D image stack Production
TAG i-5F4E3D2A instance database_server
TAG i-5F4E3D2A instance stack Production
TAG i-12345678 instance webserver
TAG i-12345678 instance stack Test
```

The following example describes the tags for the resource with ID emi-1A2B3C4D.

```
ec2-describe-tags --filter "resource-id=emi-1A2B3C4D"
TAG   emi-1A2B3C4D  image  database_server
TAG   emi-1A2B3C4D  image  stack    Production
```

The following example describes the tags for all your instances.

```
ec2-describe-tags --filter "resource-type=instance"
TAG   i-5F4E3D2A  instance  database_server
TAG   i-5F4E3D2A  instance  stack    Production
TAG   i-12345678  instance  webserver
TAG   i-12345678  instance  stack    Test
```

The following example describes the tags for all your instances that have a tag with the key webserver.

```
ec2-describe-tags --filter "resource-type=instance" --filter
"key=database_server"
TAG   i-5F4E3D2A  instance  database_server
```

The following example describes the tags for all your instances that have a tag with the key stack that has a value of either Test or Production.

```
ec2-describe-tags --filter "resource-type=instance" --filter
"key=stack"
--filter "value=Test" --filter "value=Production"
TAG   i-5F4E3D2A  instance  stack    Production
TAG   i-12345678  instance  stack    Test
```

The following example describes the tags for all your instances that have a tag with the key Purpose that has no value.

```
ec2-describe-tags --filter "resource-type=instance" --filter
"key=Purpose" --filter "value="
```

Change a Tag's Value

To change a tag's value:

Enter the following command and parameters:

```
euca-create-tags [resource] --tag [key=value]
```

Eucalyptus returns a the resource identifier and its tag key and value.

The following example changes the value of the stack tag for one of your EMIs from prod to test:

```
euca-create-tags emi-1a2b3c4d --tag stack=dev
TAG   emi-1a2b3c4d  image  stack    dev
```

Delete a Tag

To delete a tag:

Enter the following command and parameters:

```
euca-delete-tags resource_id [resource_id]" --tag
"key=[key_value]" --tag "value=[key_value]"
```

Tip: If you specify a value, the tag is deleted only if its value matches the one you specified. If you specify an empty string as the value, the tag is deleted only if the tag's value is an empty string.

Eucalyptus does not return a message.

The following example deletes two tags assigned to an EMI and an instance:

```
euca-delete-tags emi-1A2B3C4D i-6F5D4E3A --tag appserver --tag
stack
```

The following example deletes a tag only if the value is an empty string:

```
euca-delete-tags snap-1A2B3C4D --tag Owner=
```

Filter by Tag

You can describe your resources and filter the results based on the tags. To filter by tag:

Enter the following command and parameter:

```
euca-describe-tags --filter resource-type=[resource_type]
```

The following example describes all your tags.

```
euca-describe-tags
TAG emi-1A2B3C4D image appserver
TAG emi-1A2B3C4D image stack dev
TAG i-5F4E3D2A instance appserver
TAG i-5F4E3D2A instance stack dev
TAG i-12345678 instance database_server
TAG i-12345678 instance stack test
```

The following example describes the tags for a resource with ID emi-1A2B3C4D.

```
euca-describe-tags --filter "resource-id=emi-1A2B3C4D"
TAG emi-1A2B3C4D image appserver
TAG emi-1A2B3C4D image stack dev
```

The following example describes the tags for all your instances.

```
euca-describe-tags --filter "resource-type=instance"
TAG i-5F4E3D2A instance appserver
TAG i-5F4E3D2A instance stack dev
TAG i-12345678 instance database_server
TAG i-12345678 instance stack test
```

Managing Access

Eucalyptus manages access to the cloud by policies attached to accounts, groups, and users. This section details access-related tasks you can perform once your administrator allows you access to Eucalyptus. These tasks are split into the following areas: tasks for groups, and tasks for users, and tasks for credential management.

Groups

Groups are used to share resource access authorizations among a set of users within an account. Users can belong to multiple groups.

Important: A group in the context of access is not the same as a security group.

This section details tasks that can be performed on groups.

Create a Group

To create a group perform the steps listed in this topic.

Enter the following command:

```
euare-groupcreate -g <group_name>
```

Eucalyptus does not return anything.

Add a Group Policy

To add a group policy perform the steps listed in this topic.

Enter the following command:

```
euare-groupaddpolicy -g <group_name> -p <policy_name> -e <effect> -a  
  <actions> -o
```

The optional `-o` parameter tells Eucalyptus to return the JSON policy, as in this example:

```
{"Version":"2008-10-17","Statement":[{"Effect":"Allow","Action":  
["ec2:RunInstances"], "Resource":["*"]}]}
```

Modify a Group

To modify a group perform the steps listed in this topic.

Modifying a group is similar to a "move" operation. Whoever wants to modify the group must have permission to do it on both sides of the move. That is, you need permission to remove the group from its current path or name, and put that group in the new path or name.

For example, if a group changes from one area in a company to another, you can change the group's path from `/area_abc/` to `/area_efg/`. You need permission to remove the group from `/area_abc/`. You also need permission to put the group into `/area_efg/`. This means you need permission to call `UpdateGroup` on both `arn:aws:iam::123456789012:group/area_abc/*` and `arn:aws:iam::123456789012:group/area_efg/*`.

1. Enter the following command to modify the group's name:

```
euare-groupmod -g <group_name> --new-group-name <new_name>
```

Eucalyptus does not return a message.

2. Enter the following command to modify a group's path:

```
euare-groupmod -g <group_name> -p <new_path>
```

Eucalyptus does not return a message.

Add a User to a Group

To add a user to a group perform the steps listed in this topic.

Enter the following command:

```
euare-groupadduser -g <group_name> -u <user_name>
```

Remove a User from a Group

To remove a user from a group perform the steps listed in this topic.

Enter the following command:

```
euare-groupremoveuser -g <group_name> -u <user_name>
```

List Groups

To list groups perform the steps listed in this topic.

Enter the following command:

```
euare-grouplistbypath
```

Eucalyptus returns a list of paths followed by the ARNs for the groups in each path. For example:

```
arn:aws:iam::eucalyptus:group/groupa
```

Delete a Group

To delete a group perform the steps listed in this topic.

When you delete a group, you have to remove users from the group and delete any policies from the group. You can do this with one command, using the `euare-groupdel` command with the `-r` option. Or you can follow the following steps to specify who and what you want to delete.

1. Individually remove all users from the group.

```
euare-groupremoveuser -g <group_name> -u <user_name>
```

2. Delete the policies attached to the group.

```
euare-groupdelpolicy -g <group_name> -p <policy_name>
```

3. Delete the group.

```
euare-groupdel -g <group_name>
```

The group is now deleted.

Users

Users are subsets of accounts and are added to accounts by an appropriately credentialed administrator. While the term **user** typically refers to a specific person, in Eucalyptus, a **user** is defined by a specific set of credentials generated to enable access to a given account. Each set of user credentials is valid for accessing only the account for which they were created. Thus a user only has access to one account within a Eucalyptus system. If an individual person wishes to have access to more than one account within a Eucalyptus system, a separate set of credentials must be generated (in effect a new ‘user’) for each account (though the same username and password can be used for different accounts).

When you need to add a new user to your Eucalyptus cloud, you'll go through the following process:

1	<u>Create a user</u>
2	<u>Add user to a group</u>
3	<u>Give user a login profile</u>

Add a User

To add a user, perform the steps in this topic.

Enter the following command

```
euare-usercreate -u <user_name> -g <group_name> -k
```

Eucalyptus does not return a response.

Tip: If you include the `-v` parameter, Eucalyptus returns a response that includes the user's ARN and GUID.

Create a Login Profile

To create a login profile, perform the tasks in this topic.

Enter the following command:

```
euare-useraddloginprofile -u <user_name> -p <password>
```

Eucalyptus does not return a response.

Modify a User

Modifying a user is similar to a "move" operation. To modify a user, you need permission to remove the user from the current path or name, and put that user in the new path or name.

For example, if a user changes from one team in a company to another, you can change the user's path from `/team_abc/` to `/team_efg/`. You need permission to remove the user from `/team_abc/`. You also need permission to put the user into `/team_efg/`. This means you need permission to call `UpdateUser` on both `arn:aws:iam::123456789012:user/team_abc/*` and `arn:aws:iam::123456789012:user/team_efg/*`.

To rename a user:

1. Enter the following command to rename a user:

```
euare-usermod -u <user_name> --new-user-name <new_name>
```

Eucalyptus does not return a message.

2. Enter the following command:

```
euare-groupmod -u <user_name> -p <new_path>
```

Eucalyptus does not return a message.

Change User Path

Enter the following command:

```
euare-groupmod -u <user_name> -p <new_path>
```

Eucalyptus does not return a message.

Change User Password

To change a user's password using the CLI:

Enter the following command:

```
euare-usermodloginprofile -u [username] -p [password]
```

Eucalyptus does not return a message.

List Users

To list users within a path, perform the steps in this topic.

Use the `euare-userlistbypath` command to list all the users in an account or to list all the users with a particular path prefix. The output lists the ARN for each resulting user.

```
euare-userlistbypath -p <path>
```

Delete a User

To delete a user, perform the tasks in this topic.

Enter the following command

```
euare-userdel -u <user_name>
```

Eucalyptus does not return a response.

Credentials

Eucalyptus uses different types of credentials for different purposes. This section details tasks needed to allow access to Eucalyptus services.

Create Credentials

The first time you get credentials using the Eucalyptus Administrator Console, a new secret access key is generated. On each subsequent request to get credentials, an existing active secret Key is returned. You can also generate new keys using the `euare-useraddkey` command.

Tip: Each request to get a user's credentials generates a new pair of a private key and X.509 certificate.

- To generate a new key for a user by an account administrator, enter the following

```
euare-useraddkey USERNAME
```

- To generate a private key and an X.509 certificate pair, enter the following:

```
euare-usercreatecert USERNAME
```

Upload a Certificate

To upload a certificate provided by a user:

Enter the following command:

```
euare-useraddcert -u <user_name> -f <cert_file>
```

Using VM Networking and Security

Eucalyptus provides networking modes that administrators can configure according to the network and security needs of the enterprise.

Depending on the current networking mode configuration, users may have access to such features as elastic IPs, which are public (external) IP addresses that users can reserve and dynamically associate with VM instance; and security groups, which are sets of firewall rules applied to VM instances associated with the group. Euca2ools provides a means for users to interact with these features with commands for allocating and associating IP addresses, as well as creating, deleting, and modifying security groups.

Associate an IP Address with an Instance

To associate an IP address with an instance:

1. Allocate an IP address:

```
euca-allocate-address ADDRESS <IP_address>
```

2. Associate the allocated IP address with an instance ID:

```
euca-associate-address -i <instance_ID> <IP_address>
```

```
euca-associate-address -i i-56785678 192.168.17.103
```

Release an IP Address

Use euca-disassociate-address and euca-release-address to disassociate an IP address from an instance and to release the IP address to the global pool, respectively.

To release an IP address:

1. Enter the following command to disassociate an IP address from an instance:

```
euca-disassociate-address <IP_address>
```

2. Enter the following command to release an IP address:

```
euca-disassociate-address <IP_address>
```

The following example releases the IP address, 192.168.17.103

```
euca-release-address 192.168.17.103
```

Create a Security Group

Security groups let you control network access to instances by applying network rules to instances associated with a group.

To create a security group:

Enter the following command:

```
euca-add-group -d <description> <group_name>
```

Tip: You can also create a security group you run an instance. Use the `euca-run-instances` command with the `-g` option. Security group rules only apply to incoming traffic thus all outbound traffic is permitted.

The following example creates a new security group named `mygroup` and described as `newgroup`.

```
euca-add-group -d "newgroup" mygroup
```

Delete a Security Group

The `euca-delete-group` command lets you delete security groups. To delete a security group:

Enter the following command:

```
euca-delete-group <group_name>
```

The following example deletes the security group, `mygroup`.

```
euca-delete-group mygroup
```

Authorize Security Group Rules

By default, a security group prevents incoming network traffic from all sources. You can modify network rules and allow incoming traffic to security groups from specified sources using the `euca-authorize` command.

To authorize security group rules:

1. Use `euca-authorize` to authorize port 22 access to your default group.
2. Enter the following command:

```
euca-authorize -P <protocol> -p <port_number> \
-s <CIDR_source_network> <group_name>
```

The following example allows all incoming SSH traffic on port 22 to access to the security group `mygroup`. The CIDR source network, `0.0.0.0/0`, refers to any source.

```
euca-authorize -P tcp -p 22 -s 0.0.0.0/0 mygroup
GROUP mygroup #
PERMISSION mygroup ALLOWS tcp 22 22 FROM CIDR
```

Instead of specifying a CIDR source, you can specify another security group. The following example allows access to the security group `mygroup` from the `someothergroup` security group using SSH on port 22.

```
euca-authorize --source-group someothergroup \
--source-group-user someotheruser -P tcp -p 22 mygroup
```

Revoke Security Group Rules

To revoke security group rules:

Enter the following command:

```
euca-revoke -P <protocol> -p <port_number> -s <CIDR_source_network>  
<group_name>
```

The following example revokes the network rules authorized for the security group mygroup.

```
euca-revoke -P tcp -p 22 -s 0.0.0.0/0 mygroup
```

Using Auto Scaling

Eucalyptus Auto Scaling automatically adds and removes instances based on demand. Auto Scaling scales dynamically based on metrics (for example, CPU utilization). The Auto Scaling service works in conjunction with the ElasticLoad Balancing and CloudWatch services.

How Auto Scaling Works

Eucalyptus Auto Scaling is designed to address a common web application scenario: that you are running multiple copies of an application across several identical instances to adequately handle a certain volume of user requests. Eucalyptus Auto Scaling can help you make more efficient use of the computing resources in your cloud by automatically launching and terminating these instances, based on metrics and/or a schedule that you can define. There are three main Auto Scaling components that work together to provide this functionality: the *Auto Scaling group*, the *launch configuration*, and the *scaling plan*.

The *Auto Scaling group* contains the information about the instances that will be actually be used for scaling operations. The Auto Scaling group defines the minimum, desired, and maximum number of instances that you will use to scale your application.

The *launch configuration* contains all of the information necessary for Auto Scaling to launch instances, including instance type, image ID, key pairs, security groups, and block device mappings.

The *scaling policy* defines how to perform scaling actions. Scaling policies can execute automatically in response to CloudWatch alarms, or they you can execute them manually.

In addition to performing scaling operations based on the criteria defined in the scaling plan, Auto Scaling will periodically perform health checks to ensure that the instances in your Auto Scaling group are up and running. If an instance is determined to be unhealthy, Auto Scaling will terminate that instance and launch a new instance in order to maintain the minimum or desired number of instances in the scaling group.

Auto Scaling Concepts

This section discusses Auto Scaling concepts and terminology.

Understanding Launch Configurations

The launch configuration defines the settings used by the Eucalyptus instances launched within an Auto Scaling group. This includes the image name, the instance type, key pairs, security groups, and block device mappings. You associate the launch configuration with an Auto Scaling group. Each Auto Scaling group can have one (and only one) associated launch configuration.

Once you've created a launch configuration, you can't change it; you must create a new launch configuration and then associate it with an Auto Scaling group. After you've created and attached a new launch configuration to an Auto Scaling group, any new instances will be launched using parameters defined in the new launch configuration; existing instances in the Auto Scaling group are not affected.

For more information, see [Creating a Basic Auto Scaling Configuration](#).

Understanding Auto Scaling Groups

An Auto Scaling group is the central component of Auto Scaling. An Auto Scaling group defines the parameters for the Eucalyptus instances are used for scaling, as well as the minimum, maximum, and (optionally) the desired number of instances to use for Auto Scaling your application. If you don't specify the desired number of instances in your Auto Scaling group, the default value will be the same as the minimum number of instances defined.

In addition to instance and capacity definitions, each Auto Scaling group must specify one (and only one) launch configuration.

For more information, see [Creating a Basic Auto Scaling Configuration](#).

Understanding Auto Scaling Policies

An Auto Scaling policy defines how to perform scaling actions in response to CloudWatch alarms. Auto scaling policies can either *scale-in*, which terminates instances in your Auto Scaling group, or *scale-out*, which will launch new instances in your Auto Scaling group. You can define an Auto Scaling policy based on demand, or based on a fixed schedule.

Demand-Based Auto Scaling Policies

Demand-based Auto Scaling policies scale your application dynamically based on CloudWatch metrics (such as average CPU utilization) gathered from the instances running in your scaling group. For example, you can configure a CloudWatch alarm to monitor the CPU usages of the instances in your Auto Scaling group. A CloudWatch alarm definition includes *thresholds* - minimum and maximum values for the defined metric - that will cause the alarm to fire.

Note: For more information on CloudWatch, go to [Using CloudWatch](#).

For example, you can define the lower and upper thresholds of the CloudWatch alarm at 40% and 80% CPU usage. Once you've created the CloudWatch alarm, you can create a scale-out policy that launches 10 new instances when the CloudWatch alarm breaches the upper threshold (the average CPU usage is at or above 80%), and a scale-in policy that terminates 10 instances when the CloudWatch alarm breaches the lower threshold (the average CPU usage of the instances in the Auto Scaling group falls below 40%). Your Auto Scaling group will execute the appropriate Auto Scaling policy when it receives the message from the CloudWatch alarm.

Cooldown Period

A *cooldown period* is the amount of time after an Auto Scaling activity takes place where further Auto Scaling activity is suspended. This is to allow time for the Auto Scaling activities (such as new instance launches or terminations) to fully complete so that resources are not unnecessarily launched or terminated. You can specify this amount of time; if you don't specify a cooldown period, Auto Scaling uses a default cooldown period of 300 seconds (5 minutes).

For more information, go to [Configuring a Demand-Based Scaling Policy](#).

Understanding Health Checks

Auto scaling periodically performs *health checks* on the instances in your Auto Scaling group. By default, Auto Scaling group determines the health state of each instance by periodically checking the results of Eucalyptus instance status checks. When Auto Scaling determines that an instance is unhealthy, it terminates that instance and launches a new one.

If your Auto Scaling group is using elastic load balancing, Auto Scaling can determine the health status of the instances by checking the results of both Eucalyptus instance status checks and elastic load balancing instance health.

Auto scaling determines an instance is unhealthy if the calls to either Eucalyptus instance status checks or elastic load balancing instance health status checks return any state other than OK (or InService).

If there are multiple elastic load balancers associated with your Auto Scaling group, Auto Scaling will make health check calls to each load balancer. If any of the health check calls return any state other than InService, that instance will be marked as unhealthy. After Auto Scaling marks an instance as unhealthy, it will remain marked in that state, even if subsequent calls from other load balancers return an InService state for the same instance.

For more information, go to [Configuring Health Checks](#).

Understanding Instance Termination Policies

Before Auto Scaling selects an instance to terminate, it first identifies the availability zone used by the group that contains the most instances. If all availability zones have the same number of instances, Auto Scaling selects a random availability zone, and then uses the termination policy to select the instance within that randomly selected availability zone for termination.

By default, Auto Scaling chooses the instance that was launched with the oldest launch configuration. If more than one instance was launched using the oldest launch configuration, Auto Scaling the instance that was created first using the oldest launch configuration.

You can override the default instance termination policy for your Auto Scaling group with one of the following options:

Option	Description
OldestInstance	The oldest instance in the Auto Scaling group should be terminated.
NewestInstance	The newest instance in the Auto Scaling group should be terminated.
OldestLaunchConfiguration	The first instance created using the oldest launch configuration should be terminated.
Default	Use the default instance termination policy.

You can have more than one termination policy per Auto Scaling group. The termination policies are executed in the order they were created.

For more information, go to [Configuring an Instance Termination Policy](#).

Auto Scaling Usage Examples

This section contains examples of many common usage scenarios for Auto Scaling.

Creating a Basic Auto Scaling Configuration

Auto scaling requires two basic elements to function properly: a launch configuration and an Auto Scaling group. The following examples show how to set up the basic elements of an Auto Scaling configuration.

Create a Launch Configuration

The launch configuration specifies the parameters that Auto Scaling will use when launching new instances for your Auto Scaling group. In this example, we will create a launch configuration with the minimum required parameters - in this case, we set up a launch configuration that specifies that all instances launched in the Auto Scaling group will be of instance type `m1.small` and use the `emi-00123456` image.

To create a launch configuration:

1. Enter the following command:

```
euscale-create-launch-config MyLaunchConfig --image-id emi-00123456 --instance-type m1.small
```
2. To verify the launch configuration, enter the following command:

```
euscale-describe-launch-configs MyLaunchConfig
```

You should see output similar to the following:

```
LAUNCH-CONFIG MyLaunchConfig emi-00123456 m1.small
```

You've now created a launch configuration..

Create an Auto Scaling Group

The Auto Scaling group contains settings like the minimum, maximum, and desired number of Eucalyptus instances. At minimum, you must specify the name of the Auto Scaling group, the name of an existing launch configuration, the availability zone, and the minimum and maximum number of instances that should be running. In the following example, we will create an Auto Scaling group called MyScalingGroup in availability zone PARTI00, with a minimum size of 2 and a maximum size of 5.

To create an Auto Scaling group:

1. Enter the following command:

```
euscale-create-auto-scaling-group MyScalingGroup --launch-configuration
                                   MyLaunchConfig --availability-zones PARTI00 --min-size
2 --max-size 5
                                   --desired-capacity 2
```

2. Enter the following command to verify the Auto Scaling group you just created:

```
euscale-describe-auto-scaling-groups MyScalingGroup
```

This command will return output similar to the following:

```
AUTO-SCALING-GROUP MyScalingGroup MyLaunchConfig PARTI00 2 5 2 Default
INSTANCE i-1B853EC3 PARTI00 InService Healthy MyLaunchConfig
INSTANCE i-ABC53ED7 PARTI00 InService Healthy MyLaunchConfig
```

Once you've created the Auto Scaling group, Auto Scaling will launch the appropriate number of instances.

Configuring a Demand-Based Scaling Policy

An Auto Scaling group needs a scaling policy to determine when to perform scaling activities. Auto scaling policies work with CloudWatch to identify metrics and set alarms, which are triggered when the metrics fall outside of a specified value range. To configure a scale-based policy, you need to create the policy, and then create CloudWatch alarms to associate with the policy.

In the following example, we will create a demand-based scaling policy.

Note: For more information on CloudWatch, go to [Using CloudWatch](#).

Create Auto Scaling Policies

To create the scaling policies:

1. Create a scale-out policy using the following command:

```
euscale-put-scaling-policy MyScaleoutPolicy --auto-scaling-group
MyScalingGroup --adjustment=30 --type PercentChangeInCapacity
```

This command will return a unique Amazon Resource Name (ARN) for the new policy.

Note: You will need this ARN to create the Cloudwatch alarms in subsequent steps.

Note: The following example has been split into two lines for legibility.

```
arn:aws:autoscaling::706221218191:scalingPolicy:5d02981b-
f440-4c8f-98f2-8a620dc2b787:
    autoScalingGroupName/MyScalingGroup:policyName/MyScaleoutPolicy
```

2. Create a scale-in policy using the following command:

```
euscale-put-scaling-policy MyScaleinPolicy -g MyScalingGroup --adjustment=-2
--type ChangeInCapacity
```

This command will return output containing a unique Amazon Resource Name (ARN) for the new policy, similar to the following:

Note: You will need this ARN to create the Cloudwatch alarms in subsequent steps.

Note: The following example has been split into two lines for legibility.

```
arn:aws:autoscaling::706221218191:scalingPolicy:d28c6ffc-e9f1-4a48-
a79c-8b431794c367:
  autoScalingGroupName/MyScalingGroup:policyName/MyScaleinPolicy
```

Create CloudWatch Alarms

To create CloudWatch alarms:

1. Create a Cloudwatch alarm for scaling out when the average CPU usage exceeds 80 percent:

Note: The following example has been split into multiple lines for legibility.

```
euwatch-put-metric-alarm AddCapacity --metric-name CPUUtilization --unit
Percent
--namespace "AWS/EC2" --statistic Average --period 120 --threshold 80 --
comparison-operator
GreaterThanOrEqualToThreshold --dimensions
"AutoScalingGroupName=MyScalingGroup"
--evaluation-periods 2 --alarm-actions
arn:aws:autoscaling::706221218191:scalingPolicy:5d02981b-
f440-4c8f-98f2-8a620dc2b787:
  autoScalingGroupName/MyScalingGroup:policyName/MyScaleoutPolicy
```

2. Create a Cloudwatch alarm for scaling in when the average CPU usage falls below 40 percent:

Note: The following example has been split into multiple lines for legibility.

```
euwatch-put-metric-alarm RemoveCapacity --metric-name CPUUtilization --unit
Percent
--namespace "AWS/EC2" --statistic Average --period 120 --threshold 40 --
comparison-operator
LessThanOrEqualToThreshold --dimensions
"AutoScalingGroupName=MyScalingGroup" --evaluation-periods 2
--alarm-actions
arn:aws:autoscaling::706221218191:scalingPolicy:d28c6ffc-e9f1-4a48-
a79c-8b431794c367:
  autoScalingGroupName/MyScalingGroup:policyName/MyScaleinPolicy
```

Verify Your Alarms and Policies

Once you've created your Auto Scaling policies and CloudWatch alarms, you should verify them.

To verify your alarms and policies:

1. Use the CloudWatch command `euwatch-describe-alarms` to see a list of the alarms you've created:

```
euwatch-describe-alarms
```

This will return output similar to the following:

```
AddCapacity INSUFFICIENT_DATA
arn:aws:autoscaling::706221218191:scalingPolicy:5d02981b-
f440-4c8f-98f2-8a620dc2b787:
  autoScalingGroupName/MyScalingGroup:policyName/MyScaleoutPolicy
AWS/EC2 CPUUtilization 120 Average 2 GreaterThanOrEqualToThreshold 80.0
RemoveCapacity INSUFFICIENT_DATA
arn:aws:autoscaling::706221218191:scalingPolicy:d28c6ffc-e9f1-4a48-
a79c-8b431794c367:
  autoScalingGroupName/MyScalingGroup:policyName/MyScaleinPolicy
AWS/EC2 CPUUtilization 120 Average 2 LessThanOrEqualToThreshold 40.0
```

2. Use the `euscale-describe-policies` command to see the scaling policies you've created:

```
euscale-describe-policies --auto-scaling-group MyScalingGroup
```

This will return output similar to the following (note that this output has been split into multiple lines for legibility):

```
SCALING-POLICY MyScalingGroup MyScaleinPolicy -2 ChangeInCapacity
arn:aws:autoscaling::706221218191:
  scalingPolicy:d28c6ffc-e9f1-4a48-a79c-8b431794c367:
  autoScalingGroupName/MyScalingGroup:policyName/MyScaleinPolicy
SCALING-POLICY MyScalingGroup MyScaleoutPolicy 30 PercentChangeInCapacity
arn:aws:autoscaling::706221218191:
  scalingPolicy:5d02981b-f440-4c8f-98f2-8a620dc2b787:
  autoScalingGroupName/MyScalingGroup:policyName/MyScaleoutPolicy
```

Configuring Health Checks

By default, Auto Scaling group determines the health state of each instance by periodically checking the results of instance status checks. You can specify using the ELB health check method in addition to using the instance health check method.

To use load balancing health checks for an Auto Scaling group:

Use the following command to specify ELB health checks for an Auto Scaling group:

```
euscale-update-auto-scaling-group MyScalingGroup --health-check-type ELB --
  grace-period 300
```

Configuring an Instance Termination Policy

You can control how Auto Scaling determines which instances to terminate. You can specify a termination policy when you create an Auto Scaling group, and you can change the termination policy at any time using the `euscale-update-auto-scaling-group` command.

You can override the default instance termination policy for your Auto Scaling group with one of the following options:

Option	Description
OldestInstance	The oldest instance in the Auto Scaling group should be terminated.
NewestInstance	The newest instance in the Auto Scaling group should be terminated.
OldestLaunchConfiguration	The first instance created using the oldest launch configuration should be terminated.
Default	Use the default instance termination policy.

To configure an instance termination policy:

1. Specify the `--termination-policies` parameter when creating or updating the Auto Scaling group. For example:

```
euscale-update-auto-scaling-group MyScalingGroup --termination-policies
  "NewestInstance"
```

2. Verify that your Auto Scaling group has updated the termination policy by running the following command:
`euscale-describe-auto-scaling-groups MyScalingGroup`

This command should return output similar to the following:

```
AUTO-SCALING-GROUP MyScalingGroup MyLaunchConfig PARTI00 2 5 2
  NewestInstance
INSTANCE i-1B853EC3 PARTI00 InService Healthy MyLaunchConfig
INSTANCE i-ABC53ED7 PARTI00 InService Healthy MyLaunchConfig
```

Configuring Auto Scaling with Elastic Load Balancing

This example shows how to set up Auto Scaling with Elastic Load Balancing.

To set up a load-balanced auto scaling configuration:

1. If you don't already have a launch configuration, create one:
`euscale-create-launch-config MyLaunchConfig --image-id emi-50783D25 --instance-type m1.medium --group mysecuritygroup`
2. Create a new auto scaling group associated with a load balancer:
`euscale-create-auto-scaling-group MyScalingGroup --launch-configuration MyLaunchConfig --load-balancers MyLoadBalancer --availability-zones AcmeAvailabilityZone --min-size 2 --max-size 4`
3. Authorize the security group used by the load balancer for back-end port communication. For example:

```
$ eulb-describe-lbs --show-long
LOAD_BALANCER MyLoadBalancer
MyLoadBalancer-408396244283.elb.acme.eucalyptus-systems.com
{interval=200,target=HTTP:80/,timeout=3,healthy-threshold=2,unhealthy-
threshold=4} AcmeAvailabilityZone
{protocol=HTTP,lb-port=80,instance-protocol=HTTP,instance-port=80}
{owner-alias=944786667073,group-name=euca-internal-408396244283-
MyLoadBalancer}
2014-05-28T18:13:17.902Z
```

```
euca-authorize mysecuritygroup -u 944786667073 -o euca-
internal-408396244283-MyLoadBalancer -p -1
```

4. Verify that your Auto Scaling group has been created with a load balancer:

```
$ euscale-describe-auto-scaling-groups
AUTO-SCALING-GROUP MyScalingGroup MyLaunchConfig AcmeAvailabilityZone
MyLoadBalancer 2 4 2 Default
INSTANCE i-DFCD0CBC AcmeAvailabilityZone InService Healthy MyLaunchConfig
INSTANCE i-B3431043 AcmeAvailabilityZone InService Healthy MyLaunchConfig
```

Using Elastic Load Balancing

Elastic Load Balancing automatically distributes incoming traffic across your Eucalyptus cloud. It enables you to achieve even greater fault tolerance by automatically detecting instances that are overloaded, and rerouting traffic to other instances as needed.

Elastic Load Balancing works in conjunction with Eucalyptus's Auto Scaling and Cloud Watch services, to make your cloud more robust and efficient.

The following section describes how load balancing works, provides an overview of load balancing concepts, and includes a series of usage scenarios that will show you how to perform common load balancing tasks.

Elastic Load Balancing Overview

Elastic Load Balancing is designed to provide an easy-to-use fault tolerant cloud platform. Using Elastic Load Balancing, you can automatically balance incoming traffic, ensuring that requests are sent to an instance that has the capacity to serve them. It allows you to add and remove instances as needed, without interrupting the operation of your cloud. If an instance fails or is removed, the load balancer stops routing traffic to that instance. If that instance is restored, or an instance is added, the load balancer automatically resumes or starts routing traffic to that instance.

If your cloud is serving traffic over HTTP, the Elastic Load Balancing service can provide session stickiness, allowing you to bind specific virtual instances to your load balancers.

Elastic Load Balancing can balance requests within a cluster, or across multiple clusters. If there are no more healthy instances in a cluster, the load balancer will route traffic to other clusters, until healthy instances are restored to that cluster.

Elastic Load Balancing Concepts

This section describes the terminology and concepts you need for understanding and using the Elastic Load Balancing service.

DNS

When a new load balancer is created, Eucalyptus will assign a unique DNS A record to the load balancer. After the load balancer has been launched and configured, the IP address of its interface will be added to the DNS name. If more than one cluster is specified, there can be more than one IP addresses mapped to the DNS name.

The load balancers in one cluster will distribute traffic to the instances only in the same cluster. Application users can query the application service using the DNS name and the Eucalyptus DNS service will respond to the query with the list of IP addresses on a round-robin basis.

Eucalyptus generates a DNS name automatically (e.g., lb001.euca-cloud.example.com). Typically there will also be a CNAME record that maps from the meaningful domain name (e.g., service.example.com) to the automatically-generated DNS name. The CNAME records can be serviced anywhere on Internet.

Health Check

In order to route traffic to healthy instances, and prevent traffic from being routed to unhealthy instances, the Elastic Load Balancing service routinely checks the health of your service instances. The health check uses metrics such as latency, RequestCount and HTTP response code counts to ensure that service instances are responding appropriately to user traffic.

Load Balancer

Load balancers are the core of the Elastic Load Balancing service. Load balancers are special instances created from a Eucalyptus-provided VM image, and are managed by Eucalyptus. Instances off the image forward packets to your service instances using load-balancing software to ensure no instances are overloaded.

There may be a brief delay between the time that the first service instance is registered to a load balancer and the time the load balancer becomes operational. This is due to the virtual machine instantiation, and will not adversely affect the operation of your load balancer.

Each balancer VM will service only one load balancer. Launching unnecessary load balancers may be detrimental to your cloud's performance.

Service Instance

A service instance is an instance created from an image in your cloud. These are the instances that serve your application and users. The Elastic Load Balancing service monitors the health of these instances and routes traffic only to healthy instances.

Sticky Sessions

By default, a load balancer routes each request independently to the application instance with the smallest load. However, you can use the sticky session feature (also known as session affinity), which enables the load balancer to bind a user's session to a specific application instance. This ensures that all requests coming from the user during the session will be sent to the same application instance.

The key to managing the sticky session is determining how long your load balancer should consistently route the user's request to the same application instance. If your application has its own session cookie, then you can set Elastic Load Balancing to create the session cookie to follow the duration specified by the application's session cookie. If your application does not have its own session cookie, then you can set Elastic Load Balancing to create a session cookie by specifying your own stickiness duration. You can associate stickiness duration for only HTTP/HTTPS load balancer listeners.

An application instance must always receive and send two cookies: A cookie that defines the stickiness duration and a special Elastic Load Balancing cookie named AWSELB, that has the mapping to the application instance.

HTTPS/SSL Support

HTTPS Support is a feature that allows you to use the SSL/TLS protocol for encrypted connections (also known as SSL offload). This feature enables traffic encryption between the clients that initiate HTTPS sessions with your load balancer and also for connections between the load balancer and your back-end instances.

There are several advantages to using HTTPS/SSL connections with your load balancer:

- The SSL server certificate used to terminate client connections can be managed centrally on the load balancer, rather than on every individual application instance.
- The work of encrypting and decrypting SSL traffic is moved from the application instance to the load balancer.
- The load balancer can ensure session affinity or "sticky sessions" by terminating the incoming HTTPS request and then re-encrypting the content to send to the back-end application instance.
- All of the features available for HTTP can be used with HTTPS connections.

Using HTTPS/SSL protocols for both front-end and back-end connections ensures end-to-end traffic encryption. If you are using SSL and do not want Elastic Load Balancing to terminate, you can use a TCP listener and install certificates on all the back-end instances handling requests.

To enable HTTPS support for your load balancer, you'll have to install an SSL server certificate on your load balancer by using Identity and Access Management (IAM) to upload your SSL certificate and key. After you upload your certificate, specify its Amazon Resource Name (ARN) when you create a new load balancer or update an existing load balancer. The load balancer uses the certificate to terminate and then decrypt requests before sending them to the back-end instances.

Eucalyptus Load Balancing Usage Examples

This section contains examples of common usage scenarios for Eucalyptus Load Balancing.

Eucalyptus ELB Listener Configurations

This section provides a reference to various possible ways to configure your listener, depending on how secure you want your load balancer. Currently, Eucalyptus supports the following HTTP/HTTPS Load Balancer use cases:

- Basic HTTP load balancer
- Secure website or application using ELB to offload SSL decryption.
- Secure website or application using end-to-end encryption

Use Case	Front-end Protocol	Front-end Options	Back-end Protocol	Back-end Options	Notes
Basic HTTP load balancer	HTTP	NA	HTTP	NA	Supports X-forward for header. Go to AWS X-forwarding for more information.
Secure website or application using Elastic Load Balancing to offload SSL decryption	HTTPS	SSL Negotiation. See Updating the SSL Negotiation Configuration .	HTTP	NA	Supports X-forward for header. Go to AWS X-forwarding for more information. Requires an SSL certificate installed on the load balancer. For instructions, see Uploading SSL Certificates for Elastic Load Balancing .

Use Case	Front-end Protocol	Front-end Options	Back-end Protocol	Back-end Options	Notes
Secure website or application using end-to-end encryption	HTTPS	SSL Negotiation. See Updating the SSL Negotiation Configuration .	HTTPS	Back-end authentication	Supports X-forward for header. Go to AWS X-forwarding for more information. Requires an SSL certificate installed on the load balancer and registered instances. For instructions, see Uploading SSL Certificates for Elastic Load Balancing and Register instances with the Load Balancer.

Creating a Basic Elastic Load Balancing Configuration

Elastic load balancing requires two basic elements to function properly: a load balancer and instances registered with that load balancer. The following examples show how to set up the basic elements of an elastic load balancer configuration.

Create a Load Balancer

The load balancer manages incoming traffic, and monitors the health of your instances. The load balancer ensures that traffic is only sent to healthy instances.

To create a load balancer:

1. Enter the following command, specifying availability zones:

```
eulb-create-lb -z one -l "lb-port=80, protocol=HTTP, instance-port=80, instance-protocol=HTTP" MyLoadBalancer
```

2. To verify the elastic load balancer has been created, enter the following command:

```
eulb-describe-lbs MyLoadBalancer
```

You should see output similar to the following:

```
LOAD_BALANCER MyLoadBalancer MyLoadBalancer-587773761872.lb.localhost
2013-01-01T01:23:45.678Z
```

3. Optionally, you can create listeners for the load balancer as follows:

```
eulb-create-lb-listeners --listener "lb-port=80, protocol=HTTP, instance-port=80, instance-protocol=HTTP"
```

You've now created an elastic load balancer.

Register instances with the Load Balancer

The load balancer monitors the health of registered instances, and balances incoming traffic across the healthy instances.

To register an instance with the load balancer:

1. Enter the following command:

```
eulb-register-instances-with-lb --instances i-e0636aca,i-0c9c3967
MyLoadBalancer
```

2. Enter the following command to verify that the instances are registered with the load balancer:

```
eulb-describe-instance-health MyLoadBalancer
```

This command will return output similar to the following:

```
INSTANCE i-6FAD3F7B InService
INSTANCE i-70FE4541 InService
```

Once you've created the load balancer and registered your instances with it, the load balancer will automatically route traffic from its endpoint URL to healthy instances.

Configuring the Health Check

To determine which instances are healthy, the load balancer periodically polls the registered instances. You can use the `eulb-configure-healthcheck` command as described in this topic.

Perform the following step to configure how the instances should be polled, how long to wait for a response, and how many consecutive successes or failures are required to mark an instance as healthy or unhealthy.

Note: After you initially set up your load balancer, Eucalyptus automatically performs a health check to protect against potential side-effects caused by instances being terminated without being deregistered. This health check uses the instance port defined in the load balancer configuration

The following shows an example health check configuration command:

```
eulb-configure-healthcheck --healthy-threshold 5 --unhealthy-threshold 5 --
interval 30 --timeout 120 --target HTTP:80/ MyLoadBalancer
```

Use `--healthy-threshold` and `--unhealthy-threshold` to specify the number of consecutive health checks required to mark an instance as Healthy or Unhealthy respectively. Use `--target` to specify the connection target on your instances for these health checks. Use `--interval` and `--timeout` to specify the approximate frequency and maximum duration of these health checks.

Modifying an Elastic Load Balancing Configuration

Elastic load balancing requires two basic elements to function properly: a load balancer and instances registered with that load balancer. The following examples show how to modify the basic elements of an elastic load balancer configuration.

De-register instances from the Load Balancer

The load balancer monitors the health of registered instances, and balances incoming traffic across the healthy instances.

To deregister an instance from the load balancer:

1. Enter the following command:

```
eulb-deregister-instances-from-lb --instances INSTANCE1,INSTANCE2,...
MyLoadBalancer
```

2. Enter the following command to verify that the instances are deregistered from the load balancer:

```
eulb-describe-instance-health MyLoadBalancer
```

This command will return output similar to the following:

```
INSTANCE i-6FAD3F7B InService
```

Delete Load Balancer Listeners

To delete a load balancer listener:

Enter the following command:

```
eulb-delete-lb-listeners --lb-ports PORT1,PORT2,... MyLoadBalancer
```

Delete Load Balancer

To delete a load balancer:

Enter the following command:

```
eulb-delete-lb MyLoadBalancer
```

You've now deleted the elastic load balancer.

Creating Elastic Load Balancing Sticky Sessions

By default, a load balancer routes each request independently to the application instance with the smallest load. However, you can use the sticky session feature (also known as session affinity) which enables the load balancer to bind a user's session to a specific application instance. This ensures that all requests coming from the user during the session will be sent to the same application instance.

Enable Duration-Based Session Stickiness

The load balancer uses a special load-balancer-generated cookie to track the application instance for each request. When the load balancer receives a request, it first checks to see if this cookie is present in the request. If so, the request is sent to the application instance specified in the cookie. If there is no cookie, the load balancer chooses an application instance based on the existing load balancing algorithm. A cookie is inserted into the response for binding subsequent requests from the same user to that application instance. The stickiness policy configuration defines a cookie expiration, which establishes the duration of validity for each cookie. The cookie is automatically updated after its duration expires.

In this example, you create a stickiness policy and then use it to enable sticky sessions for a load balancer that has load balancer-generated HTTP cookies. Before you get started, be sure you've created a load balancer with Elastic Load Balancing.

To enable duration-based sticky sessions for a load balancer:

1. Use the `eulb-create-lb-cookie-stickiness-policy` command to create a load-balancer-generated cookie stickiness policy with a cookie expiration period of 60 seconds.

```
eulb-create-lb-cookie-stickiness-policy MyLoadBalancer --policy-name MyLoadBalancerPolicy --expiration-period 60
```
2. Use the `eulb-set-lb-policies-of-listener` command to enable session stickiness for a load balancer using the `MyLoadBalancerPolicy`.

```
eulb-set-lb-policies-of-listener MyLoadBalancer --lb-port 80 --policy-names MyLoadBalancerPolicy
```
3. You can use the `eulb-describe-lb-policies` command to list the policies created for the load balancer.

```
eulb-describe-lb-policies MyLoadBalancer --show-long
```

Enable Application-Controlled Session Stickiness

The load balancer uses a special cookie to associate the session with the original server that handled the request, but follows the lifetime of the application-generated cookie corresponding to the cookie name specified in the policy configuration. The load balancer only inserts a new stickiness cookie if the application response includes a new application cookie. The load balancer stickiness cookie does not update with each request. If the application cookie is explicitly removed or expires, the session stops being sticky until a new application cookie is issued.

If an application server fails or is removed, the load balancer will try to route the sticky session to another healthy application server. The load balancer will try to stick to new healthy application server and continue routing to currently stick application server even after the failed application server comes back. However, it is up to the new application server on how it'll respond to a request which it has not seen previously.

In this example, you configure a load balancer for session stickiness when the life of the session follows that of an application-generated cookie. Before you get started, be sure you've created a load balancer with Elastic Load Balancing.

To enable application-controlled session stickiness:

1. Use the `eulb-create-app-cookie-stickiness-policy` command to create a load application-generated cookie stickiness policy:
`eulb-create-app-cookie-stickiness-policy my-load-balancer -p my-app-cookie-lb-policy -c my-cookie`
2. Use the `eulb-set-lb-policies-of-listener` command to enable session stickiness for a load balancer using the my-load-balancer policy.
`eulb-set-lb-policies-of-listener example-lb --lb-port 80 --policy-names my-app-cookie-lb-policy`
3. You can use the `eulb-describe-lb-policies` command to list the policies created for the load balancer.
`eulb-describe-lb-policies example-lb --show-long`

Uploading SSL Certificates for Elastic Load Balancing

You must install an X.509 certificate on your load balancer in order to use HTTPS or SSL termination. The X.509 certificate is issued by a central Certificate Authority (CA) and contains identifying information, including a digital signature. X.509 certificates have a validity period. Once an X.509 certificate expires, you must create and install a new certificate.

Upload a Certificate

Once you've created a certificate, you must upload it to your cloud using the `euare-upload-server-certificate` command.

Note: You must create the certificate and get it signed by a certificate authority (CA) before you can upload the certificate using the AWS Identity and Access Management (IAM) service. For instructions, go to [SSL Certificate for Elastic Load Balancing](#).

To upload a certificate :

- Enter the `euare-servercertupload` command, specifying the name of your certificate, the contents of the PEM-encoded public- and private-keys:

```
euare-servercertupload -s cert-name --certificate-file ssl_server_cert.crt
--private-key-file ssl_server_cert.pem
```

You've now created an elastic load balancer.

Verify Server Certificate

You can verify that an uploaded certificate is stored in IAM. Each certificate object has a unique Amazon Resource Name (ARN) and ID.

To verify an uploaded certificate:

Use the `euare-servercertlistbypath` command to verify the certificate is stored in IAM:

```
euare-servercertgetattributes -s elb-ssl-cert
```

The command will return the ARN, followed by the GUID. For example:

```
arn:aws:iam::495375389014:server-certificate/elb-ssl-cert
ASCWDKTJBXPSZTHWFERVP
```

Adding SSL Support

This topic describes how to add SSL support to a new or existing load balancer.

Creating a new listener with SSL support

This task shows how to create a new listener with SSL support.

Note: In order to use HTTPS support, you'll need to install an SSL server certificate on your load balancer. If you haven't already done this, see [Uploading SSL Certificates for Elastic Load Balancing](#).

To add a new listener to your load balancer:

1. Using the ARN for the certificate you installed, use the `eulb-create-listener` command to create a new listener. For example:

```
eulb-create-lb-listeners MyLoadBalancer --listener "protocol=HTTPS,lb-port=443,instance-port=80,instance-protocol=HTTP, cert-id=arn:aws:iam::12345678901:my-server-certificate/testing/myNewCert"
```
2. Use the `eulb-describe-lbs` command to see the details of your load balancer. For example:

```
eulb-describe-lbs MyLoadBalancer
```

Updating a listener with a new SSL certificate

This task shows how to replace an SSL server certificate configured with listeners"

Note: In order to use HTTPS support, you'll need to install an SSL server certificate on your load balancer. If you haven't already done this, see [Uploading SSL Certificates for Elastic Load Balancing](#).

To update an existing listener with SSL support:

1. Use the `eulb-set-lb-listener-ssl-cert` command with the ARN of your new server certificate to replace the certificate configured with listeners For example:

```
eulb-set-lb-listener-ssl-cert MyLoadBalancer --lb-port 443 --cert-id arn:aws:iam::12345678901:my-server-certificate/testing/myNewCert
```
2. Use the `eulb-describe-lbs` command to see the details of your load balancer. For example:

```
eulb-describe-lbs MyLoadBalancer
```

Updating the SSL Negotiation Configuration

Eucalyptus Elastic Load Balancing (ELB) uses SSL negotiation configurations to determine how SSL connections to your load balancer behave. This topic shows how to update an existing load balancer with an SSL negotiation configuration.

1. Get a list of predefined security policies using the `eulb-describe-lb-policies` command:

```
eulb-describe-lb-policies
```

This produces output similar to the following:

```
POLICY ELBSample-AppCookieStickinessPolicy AppCookieStickinessPolicyType
POLICY ELBSample-LBCookieStickinessPolicy LBCookieStickinessPolicyType
POLICY ELBSecurityPolicy-2014-10 SSLNegotiationPolicyType
POLICY ELBSecurityPolicy-2015-02 SSLNegotiationPolicyType
POLICY ELBSecurityPolicy-2011-08 SSLNegotiationPolicyType
POLICY ELBSecurityPolicy-2015-05 SSLNegotiationPolicyType
POLICY ELBSecurityPolicy-2014-01 SSLNegotiationPolicyType
```

2. Use the `eulb-create-lb-policy` command to update the SSL negotiation configuration to use one of the predefined security policies. For example:

```
eulb-create-lb-policy --policy-name mypredefinedsslpolicy --policy-type SSLNegotiationPolicyType --attributes "Reference-Security-Policy=ELBSecurityPolicy-2011-08" myloadbalancer
```

3. Use the `eulb-describe-lbs` command to verify the update. For example:
`eulb-describe-lbs myloadbalancer`

Adding and Editing Predefined Security Policies

This topic describes how to add and edit ELB security policies.

Default ELB policies are stored as JSON files in the `/etc/eucalyptus/cloud.d/elb-security-policy` directory. You can add or edit policy files here, and the changes will take effect when the CLC is restarted.

1. Copy one of the ELB policy files to a new file and edit the file. You must change the `PolicyName` attribute to a new name, with the name ending in a date. For example:

`ELBSecurityPolicy-2015-09`

The policy file with the most recent date appended to the name will be used as the default policy when users create HTTPS/SSL listeners.

The following is an example of an ELB policy file. You can modify this file and save it with a new filename in the `/etc/eucalyptus/cloud.d/elb-security-policy` directory.

```

    "AttributeValue": "false"
  },
  {
    "AttributeName": "EXP-RC2-CBC-MD5",
    "AttributeValue": "false"
  },
  {
    "AttributeName": "EXP-KRB5-RC2-CBC-SHA",
    "AttributeValue": "false"
  },
  {
    "AttributeName": "EXP-KRB5-DES-CBC-SHA",
    "AttributeValue": "false"
  },
  {
    "AttributeName": "EXP-KRB5-RC2-CBC-MD5",
    "AttributeValue": "false"
  },
  {
    "AttributeName": "EXP-KRB5-DES-CBC-MD5",
    "AttributeValue": "false"
  },
  {
    "AttributeName": "EXP-ADH-RC4-MD5",

```

```

        "AttributeValue": "false"
      },
      {
        "AttributeName": "EXP-RC4-MD5",
        "AttributeValue": "false"
      },
      {
        "AttributeName": "EXP-KRB5-RC4-SHA",
        "AttributeValue": "false"
      },
      {
        "AttributeName": "EXP-KRB5-RC4-MD5",
        "AttributeValue": "false"
      }
    ],
    "PolicyName": "ELBSecurityPolicy-2015-05",
    "PolicyTypeName": "SSLNegotiationPolicyType"
  }
}

```

- Using a text editor, change the `PolicyName` attribute. For example:
`"PolicyName": "ELBSecurityPolicy-2015-05"`
- Once you've edited and saved the JSON file, restart the CLC.
- Once the CLC has restarted, use the `eulb-describe-lb-policies` command to verify that your new policy is listed.

For example:

```

POLICY ELBSample-AppCookieStickinessPolicy AppCookieStickinessPolicyType
POLICY ELBSample-LBCookieStickinessPolicy LBCookieStickinessPolicyType
POLICY ELBSecurityPolicy-2014-10 SSLNegotiationPolicyType
POLICY ELBSecurityPolicy-2015-02 SSLNegotiationPolicyType
POLICY ELBSecurityPolicy-2011-08 SSLNegotiationPolicyType
POLICY ELBSecurityPolicy-2015-05 SSLNegotiationPolicyType
POLICY ELBSecurityPolicy-2014-01 SSLNegotiationPolicyType
POLICY MyNewELBSecurityPolicy-2015-09 SSLNegotiationPolicyType

```

You can now use your new security policy using the `eulb-create-lb-policy` command. For more information, see [Updating the SSL Negotiation Configuration](#).

Configuring Back-end Server Authentication

When running a web application with HTTPS or SSL as the backend server's protocol, you might want to authenticate the back-end servers using the public key of the back-end server's certificate. This authentication can be used to ensure that back-end servers accept only encrypted communication and to ensure that the back-end servers have the correct certificate.

To configure back-end server authentication:

- Create a new loadbalancer with HTTPS as backend instance's protocol:

```

eulb-create-lb -l "protocol=HTTPS,lb-port=443,instance-
protocol=HTTPS,instance-port=8443,cert-id=arn:aws:iam::000550595745:server-
certificate/mycert01"\
              -z one myloadbalancer

```

- Create a new `PublicKeyPolicyType` policy for the load balancer. In the example below, 'server.crt' is the file containing the public key of the backend server's certificate.

```

eulb-create-lb-policy -n webservercert -t PublicKeyPolicyType -a
"name=PublicKey, value=$(cat ./server.crt)" myloadbalancer

```

- Use the `eulb-describe-lb-policies` to ensure that the policy was created. For example:

```

eulb-describe-lb-policies -p webservercert myloadbalancer

```

4. Create a new `BackendServerAuthenticationPolicyType` policy that refers to the public key policy created above.

```
eulb-create-lb-policy -n webserverauthentication -t
BackendServerAuthenticationPolicyType -a "name=PublicKeyPolicyName,
value=webservercert" myloadbalancer
```

5. Make sure the policy is created. For example:

```
eulb-describe-lb-policies -p webserverauthentication myloadbalancer
```

6. Set the created policy to the listener by specifying the instance's port number. For example:

```
eulb-set-lb-policies-for-backend-server -i 443 -p webserverauthentication
myloadbalancer
```

7. Make sure the policy is attached to the intended listener. For example:

```
eulb-describe-lbs --show-long myloadbalancer
LOAD_BALANCER myloadbalancer
myloadbalancer-000550595745.lb.c-04.autoqa.qa1.eucalyptus-systems.com
{interval=30,target=TCP:8443,timeout=5,healthy-threshold=3,unhealthy-
threshold=3} one \
{protocol=HTTPS,lb-port=443,instance-protocol=HTTPS,instance-port=8443,cert-
id=arn:aws:iam::000550595745:server-certificate/mycert01,\
{ELBSecurityPolicy-2015-05}}
{instance-port=8443,policies={webserverauthentication}}
{ELBSecurityPolicy-2015-05,webservercert,webserverauthentication}
{owner-alias=000936883517,group-name=euca-internal-000550595745-
myloadbalancer}
2015-10-12T20:55:52.08Z
internet-facing
```

Enabling Cross-Zone Load Balancing

When an ELB has instances in multiple available zones, enabling cross-zone load balancing will distribute traffics to instances across availability zones. If disabled, the load balancer in a zone will distribute traffics to instances within the zone. For example, if a Zone A has 10 instances, and a Zone B has 1 instance, and the client happens to use the load balancer of Zone B (via round-robin DNS), cross-zone load balancing will ensure that the clients will use all 11 instances, not just the one instance in Zone B.

To enable cross-zone load balancing:

1. By default, cross-zone load balancing is not enabled for a new load balancer. To enable, modify the load balancer attribute using the `eulb-modify-lb-attributes` command. For example:

```
eulb-modify-lb-attributes myloadbalancer CrossZoneLoadBalancing.Enabled=true
```

2. Make sure the attribute is enabled. For example:

```
eulb-describe-lb-attributes myloadbalancer
AccessLog.Enabled false
ConnectionDraining.Enabled false
ConnectionSettings.IdleTimeout 60
CrossZoneLoadBalancing.Enabled true
```

Accessing Load Balancer Logs

To help analyze an application's performances or troubleshoot problems, you can capture detailed information for all requests coming through your load balancers. When enabled, such access logs will be captured and stored in the S3 bucket.

To access ELB logs:

1. Before enabling the access logs, update the access control of your S3 (Eucalyptus object-storage-gateway) bucket so that Eucalyptus' load balancer has write permissions. The access control list requires the canonical ID of the grantee. To obtain the canonical ID of the load balancing service:

Note: If your cloud is using VPCMIDO networking mode, use the command in the next step.

```
eulb-describe-lbs --show-long --region devops-admin@region-1
LOAD_BALANCER myloadbalancer
myloadbalancer-000476918024.lb.a-18.autoqa.qa1.eucalyptus-systems.com
{interval=30,target=TCP:80,timeout=5,healthy-threshold=3,unhealthy-
threshold=3
cash,money i-6f2a1874,i-be660343
{protocol=HTTP,lb-port=80,instance-protocol=HTTP,instance-port=80}
{owner-alias=000865102303,group-name=euca-internal-000476918024-
myloadbalancer}
2015-09-29T18:11:33.761Z
internet-facing
```

Note: Save the number at the end of the output to update the bucket's ACL in [step 3](#).

- To obtain the canonical ID of the load balancing service in VPCMIDO networking mode:

Note: If your cloud is not using VPCMIDO networking mode, use the command in the previous step.

```
euserv-describe-services --filter service-type=loadbalancing --expert
SERVICE
arn:euca:bootstrap:API_10.111.1.19:loadbalancing:API_10.111.1.19.loadbalancing/
enabled 25
http://10.111.1.19:8773/services/LoadBalancing
(eucalyptus)loadbalancing=000036660381:28323c32338354b20255a633830524c1224434cb1a5254c
```

Note: Save the number at the end of the output to update the bucket's ACL in [step 3](#).

- Use any S3 client tools to update the bucket's ACL. For example:

```
# aws --endpoint-url http://objectstorage.a-18.autoqa.qa1.eucalyptus-
systems.com:8773/ s3 s3://webserverlog
# aws --endpoint-url http://objectstorage.a-18.autoqa.qa1.eucalyptus-
systems.com:8773/ s3api put-bucket-acl --grant-write "id=000865102303" --
bucket s3://webserverlog
```

- Modify your load balancer's attributes to enable the access logs. For example:

```
eulb-modify-lb-attributes myloadbalancer AccessLog.Enabled=true
AccessLog.S3BucketName=webserverlog AccessLog.EmitInterval=5
AccessLog.S3BucketPrefix=myprefix
```

- Check that the attribute has been updated correctly by using the `eulb-describe-lb-attributes` command:

```
eulb-describe-lb-attributes myloadbalancer
AccessLog.EmitInterval 5
AccessLog.Enabled true
AccessLog.S3BucketName webserverlog
AccessLog.S3BucketPrefix myprefix
ConnectionDraining.Enabled false
ConnectionSettings.IdleTimeout 60
CrossZoneLoadBalancing.Enabled true
```

Using CloudWatch

CloudWatch is a Eucalyptus service that enables you to monitor, manage, and publish various metrics, as well as configure alarm actions based on data from metrics. You can use the default metrics that come with Eucalyptus, or you can use your own metrics.

CloudWatch collects raw data from your cloud's resources and generates the information into readable, near real-time metrics. These metrics are recorded for a period of two weeks. This allows you to access historical information and provides you with information about how your resource is performing.

To find out more about what CloudWatch is, see [CloudWatch Overview](#).

To find out how to use CloudWatch, see [CloudWatch Tasks](#).

CloudWatch Overview

This section describes the concepts and details you need to understand the CloudWatch service. This section also includes procedures to complete the most common tasks for CloudWatch.

CloudWatch is a Eucalyptus service that collects, aggregates, and dispenses data from your cloud's resources. This data allows you to make operational and business decisions based on actual performance metrics. You can use CloudWatch to collect metrics about your cloud resources, such as the performance of your instances. You can also publish your own metrics directly to CloudWatch.

CloudWatch monitors the following cloud resources:

- instances
- Elastic Block Store (EBS) volumes
- Auto Scaling instances
- Eucalyptus Load Balancers (ELB)

Alarms

CloudWatch alarms help you make decisions more easily by automatically making changes to the resources you are monitoring, based on rules that you define. For example, you can create alarms that initiate Auto Scaling actions on your behalf. For more information about alarm tasks, see [Configuring Alarms](#).

Common Use Cases

A common use for CloudWatch is to keep your applications and services healthy and running efficiently. For example, CloudWatch can determine that your application runs best when network traffic remains below a certain threshold level on your instances. You can then create an automated procedure to ensure that you always have the right number of instances to match the amount of traffic you have.

Another use for CloudWatch is to diagnose problems by looking at system performance before and after a problem occurs. CloudWatch helps you identify the cause and verify your fix by tracking performance in real time.

CloudWatch Concepts

This section describes the terminology and concepts you need in order to understand and use CloudWatch.

Metric

A metric is a time-ordered set of data points. You can get metric data from Eucalyptus cloud resources (like instances or volumes), or you can publish your own set of custom metric data points to CloudWatch. You then retrieve statistics about those data points as an ordered set of time-series data.

Data points represent values of a variable over time. For example you can get metrics for the CPU usage of a particular instance, or for the latency of an elastic load balancer (ELB).

Each metric is uniquely defined by a name, a namespace, and zero or more dimensions. Each data point has a time stamp, and (optionally) a unit of measure. When you request statistics, the returned data stream is identified by namespace, metric name, dimension, and (optionally) the unit. For more information about Eucalyptus-supported metrics, see [Namespaces, Metrics, and Dimensions](#).

CloudWatch stores your metric data for two weeks. You can publish metric data from multiple sources, such as incoming network traffic from dozens of different instances, or requested page views from several different web applications. You can request statistics on metric data points that occur within a specified time window.

Namespace

A namespace is a conceptual container for a collection of metrics. Eucalyptus treats metrics in different namespaces as unique. This means that metrics from different services cannot mistakenly be aggregated into the same statistical set.

Namespace names are strings you define when you create a metric. The names must be valid XML characters, typically containing the alphanumeric characters "0-9A-Za-z" plus "." (period), "-" (hyphen), "_" (underscore), "/" (slash), "#" (hash), and ":" (colon). All Eucalyptus services that provide CloudWatch data follow the convention `AWS/<service>`, such as `AWS/EC2` and `AWS/ELB`. For more information, see [Namespaces](#).

Note: A namespace name must be less than 256 characters. There is no default namespace. You must specify a namespace for each data element you put into CloudWatch.

Dimension

A dimension is a name-value pair that uniquely identifies a metric. A dimension helps you design a conceptual structure for your statistics plan. Because dimensions are part of the unique identifier for a metric, metric name, namespace, and dimension key-value pairs define unique metrics.

You specify dimensions when you create a metric with the `euwatch-put-data` command. Eucalyptus services that report data to CloudWatch also attach dimensions to each metric. You can use dimensions to filter result sets that CloudWatch queries return. For example, you can get statistics for a specific instance by calling `euwatch-get-stats` with the `InstanceID` dimension set to a specific instance ID.

For Eucalyptus metrics, CloudWatch can aggregate data across select dimensions. For example, if you request a metric in the `AWS/EC2` namespace and do not specify any dimensions, CloudWatch aggregates all data for the specified metric to create the statistic that you requested. However, CloudWatch does not aggregate across dimensions for custom metrics.

Note: You can assign up to ten dimensions to a metric.

Time Stamp

Each metric data point must be marked with a time stamp. The time stamp can be up to two weeks in the past and up to two hours into the future. If you do not provide a time stamp, CloudWatch creates a time stamp for you based on the time the data element was received.

The time stamp you use in the request must be a `dateTime` object, with the complete date plus hours, minutes, and seconds. For example: `2007-01-31T23:59:59Z`. For more information, go to <http://www.w3.org/TR/xmlschema-2/#dateTime>. Although it is not required, we recommend you provide the time stamp in the Coordinated Universal Time (UTC or Greenwich Mean Time) time zone. When you retrieve your statistics from CloudWatch, all times reflect the UTC time zone.

Unit

A unit represents a statistic's measurement in time or amount. For example, the units for the instance `NetworkIn` metric is Bytes because `NetworkIn` tracks the number of bytes that an instance receives on all network interfaces.

You can also specify a unit when you create a custom metric. Units help provide conceptual meaning to your data. Metric data points you create that specify a unit of measure, such as Percent, will be aggregated separately. The following list provides some of the more common units that CloudWatch supports:

- Seconds
- Bytes
- Bits
- Percent
- Count
- Bytes/Second (bytes per second)
- Bits/Second (bits per second)
- Count/Second (counts per second)
- None (default when no unit is specified)

Though CloudWatch attaches no significance to a unit, other applications can derive semantic information based on the unit you choose. When you publish data without specifying a unit, CloudWatch associates it with the None unit. When you get statistics without specifying a unit, CloudWatch aggregates all data points of the same unit together. If you have two otherwise identical metrics with different units, two separate data streams will be returned, one for each unit.

Statistic

A statistic is computed aggregation of metric data over a specified period of time. CloudWatch provides statistics based on the metric data points you or Eucalyptus provide. Aggregations are made using the namespace, metric name, dimensions, and the data point unit of measure, within the time period you specify. The following table describes the available statistics.

Statistic	Description
Minimum	The lowest value observed during the specified period. You can use this value to determine low volumes of activity for your application.
Maximum	The highest value observed during the specified period. You can use this value to determine high volumes of activity for your application.
Sum	All values submitted for the matching metric added together. You can use this statistic for determining the total volume of a metric.
Average	The value of Sum / SampleCount during the specified period. By comparing this statistic with the Minimum and Maximum, you can determine the full scope of a metric and how close the average use is to the Minimum and Maximum. This comparison helps you to know when to increase or decrease your resources as needed.
SampleCount	The count (number) of data points used for the statistical calculation.

Period

A period is the length of time, in seconds, associated with a specific CloudWatch statistic. Each statistic represents an aggregation of the metrics data collected for a specified period of time. You can adjust how the data is aggregated by varying the length of the period. A period can be as short as one minute (60 seconds) or as long as two weeks (1,209,600 seconds).

The values you select for the `StartTime` and `EndTime` options determine how many periods CloudWatch returns. For example, if you set values for the `Period`, `EndTime`, and `StartTime` options for 60 seconds, CloudWatch returns an aggregated set of statistics for each minute of the previous hour. If you want statistics aggregated into ten-minute blocks, set `Period` to 600. For statistics aggregated over the entire hour, use a `Period` value of 3600.

Periods are also an important part of the CloudWatch alarms feature. When you create an alarm to monitor a specific metric, you are asking CloudWatch to compare that metric to the threshold value that you supplied. You have control over how CloudWatch makes that comparison. You can specify the period over which the comparison is made, as well as how many consecutive periods the threshold must be breached before you are notified.

Aggregation

CloudWatch aggregates statistics according to a length of time that you set. You can publish as many data points as you want with the same or similar time stamps. CloudWatch aggregates these data points by period length. You can publish data points for a metric that share not only the same time stamp, but also the same namespace and dimensions.

Subsequent calls to `euwatch-get-stats` return aggregated statistics about those data points. You can even do this in one `euwatch-put-data` request. CloudWatch accepts multiple data points in the same `euwatch-put-data` call with the same time stamp. You can also publish multiple data points for the same or different metrics, with any time stamp. The size of a `euwatch-put-data` request, however, is limited to 8KB for HTTP GET requests and 40KB for HTTP POST requests. You can include a maximum of 20 data points in one `PutMetricData` request.

For large data sets that would make the use of `euwatch-put-data` impractical, CloudWatch allows you to insert a pre-aggregated data set called a `StatisticSet`. With `StatisticSets` you give CloudWatch the `Min`, `Max`, `Sum`, and `SampleCount` of a number of data points. A common use case for `StatisticSets` is when you are collecting data many times in a minute. For example, if you have a metric for the request latency of a server, it doesn't make sense to do a `euwatch-put-data` request with every request. We suggest you collect the latency of all hits to that server, aggregate them together once a minute and send that `StatisticSet` to CloudWatch.

CloudWatch doesn't differentiate the source of a metric. If you publish a metric with the same namespace and dimensions from different sources, CloudWatch treats this as a single metric. This can be useful for service metrics in a distributed, scaled system. For example, all the hosts in a web server application could publish identical metrics representing the latency of requests they are processing. CloudWatch treats these as a single metric, allowing you to get the statistics for minimum, maximum, average, and sum of all requests across your application.

Alarm

An alarm watches a single metric over a time period you set, and performs one or more actions based on the value of the metric relative to a given threshold over a number of time periods. CloudWatch alarms will not invoke actions just because they are in a particular state. The state must have changed and been maintained for a specified number of periods.

For example, [Auto Scaling](#) works with CloudWatch alarms to perform scaling activities. When an Auto Scaling activity reacts to a CloudWatch alarm, the cooldown period is the amount of time after the activity takes place where further Auto Scaling activity is suspended. This is to allow time for the Auto Scaling activities (such as new instance launches or terminations) to fully complete so that resources are not unnecessarily launched or terminated. You can specify this amount of time; if you don't specify a cooldown period, Auto Scaling uses a default cooldown period of 300 seconds (5 minutes).

After an alarm invokes an action due to a change in state, the alarm continues to invoke the action for every period that the alarm remains in the new state.

An alarm has three possible states:

- **OK:** The metric is within the defined threshold.
- **ALARM:** The metric is outside of the defined threshold.
- **INSUFFICIENT_DATA:** The alarm has just started, the metric is not available, or not enough data is available for the metric to determine the alarm state.

The following lists some common features of alarms:

- You can create up to 5000 alarms per Eucalyptus account. To create or update an alarm, use the `euwatch-put-metric-alarm` command.
- You can list any or all of the currently configured alarms, and list any alarms in a particular state using the `euwatch-describe-alarms` command.
- You can disable and enable alarms by using the `euwatch-disable-alarm-actions` and `euwatch-enable-alarm-actions` commands
- You can test an alarm by setting it to any state using the `euwatch-set-alarm-state` command. This temporary state change lasts only until the next alarm comparison occurs.
- Finally, you can view an alarm's history using the `euwatch-describe-alarm-history` command. CloudWatch preserves alarm history for two weeks. Each state transition is marked with a unique time stamp. In rare cases, your history might show more than one notification for a state change. The time stamp enables you to confirm unique state changes.

Namespaces, Metrics, and Dimensions

This section discusses the namespaces, metrics, and dimensions that CloudWatch supports for Eucalyptus services.

Namespaces

All Eucalyptus services that provide CloudWatch data use a namespace string, beginning with "AWS/". This section describes the service namespaces.

The following table lists the namespaces for services that push metric data points to CloudWatch.

Service	Namespace
Elastic Block Store	AWS/EBS
Elastic Compute Cloud	AWS/EC2
Auto Scaling	AWS/Autoscaling
Elastic Load Balancing	AWS/ELB

Instance Metrics and Dimensions

This section describes the instance metrics and dimensions available to CloudWatch.

Available Metrics for Instances

Metric	Description	Unit
CPUUtilization	The percentage of allocated EC2 compute units that are currently in use on the instance. This metric identifies the processing power required to run an application upon a selected instance.	Percent
DiskReadOps	Completed read operations from all ephemeral disks available to the instance (if your instance uses EBS, see EBS Metrics.) This metric identifies the rate at which an application reads a disk. This can be used to determine the speed in which an application reads data from a hard disk.	Count

Metric	Description	Unit
DiskWriteOps	Completed write operations to all ephemeral disks available to the instance (if your instance uses Amazon EBS, see Amazon EBS Metrics.) This metric identifies the rate at which an application writes to a hard disk. This can be used to determine the speed in which an application saves data to a hard disk.	Count
DiskReadBytes	Bytes read from all ephemeral disks available to the instance (if your instance uses Amazon EBS, see Amazon EBS Metrics.) This metric is used to determine the volume of the data the application reads from the hard disk of the instance. This can be used to determine the speed of the application.	Bytes
DiskWriteBytes	Bytes written to all ephemeral disks available to the instance (if your instance uses Amazon EBS, see Amazon EBS Metrics.) This metric is used to determine the volume of the data the application writes onto the hard disk of the instance. This can be used to determine the speed of the application.	Bytes
NetworkIn	The number of bytes received on all network interfaces by the instance. This metric identifies the volume of incoming network traffic to an application on a single instance.	Bytes
NetworkOut	The number of bytes sent out on all network interfaces by the instance. This metric identifies the volume of outgoing network traffic to an application on a single instance.	Bytes
StatusCheckFailed	A combination of <code>StatusCheckFailed_Instance</code> and <code>StatusCheckFailed_System</code> that reports if either of the status checks has failed. Values for this metric are either 0 (zero) or 1 (one.) A zero indicates that the status check passed. A one indicates a status check failure.	Count

Metric	Description	Unit
StatusCheckFailed_Instance	Reports whether the instance has passed the EC2 instance status check in the last 5 minutes. Values for this metric are either 0 (zero) or 1 (one.) A zero indicates that the status check passed. A one indicates a status check failure.	Count
StatusCheckFailed_System	Reports whether the instance has passed the EC2 system status check in the last 5 minutes. Values for this metric are either 0 (zero) or 1 (one.) A zero indicates that the status check passed. A one indicates a status check failure.	Count

Available Dimensions for Instances

You can filter the instance data using any of the dimensions in the following table.

Dimension	Description
AutoScalingGroupName	This dimension filters the data you request for all instances in a specified capacity group. An <code>AutoScalingGroup</code> is a collection of instances you define if you're using the Auto Scaling service. This dimension is available only for instance metrics when the instances are in such an Auto Scaling group.
ImageId	This dimension filters the data you request for all instances running this Eucalyptus Machine Image (EMI).
InstanceId	This dimension filters the data you request for the identified instance only. This helps you pinpoint an exact instance from which to monitor data.
InstanceType	This dimension filters the data you request for all instances running with this specified instance type. This helps you categorize your data by the type of instance running. For example, you might compare data from an <code>m1.small</code> instance and an <code>m1.large</code> instance to determine which has the better business value for your application.

EBS Metrics and Dimensions

This section describes the Elastic Block Store (EBS) metrics and dimensions available to CloudWatch.

Available Metrics for EBS

Metric	Description	Unit
VolumeReadBytes	The total number of bytes transferred in the period.	Bytes
VolumeWriteBytes	The total number of bytes transferred in the period.	Bytes

Metric	Description	Unit
VolumeReadOps	The total number of operations in the period.	Count
VolumeWriteOps	The total number of operations in the period.	Count
VolumeTotalReadTime	The total number of seconds spent by all operations that completed in the period. If multiple requests are submitted at the same time, this total could be greater than the length of the period. For example, say the period is 5 minutes (300 seconds); if 700 operations completed during that period, and each operation took 1 second, the value would be 700 seconds.	Seconds
VolumeTotalWriteTime	The total number of seconds spent by all operations that completed in the period. If multiple requests are submitted at the same time, this total could be greater than the length of the period. For example, say the period is 5 minutes (300 seconds); if 700 operations completed during that period, and each operation took 1 second, the value would be 700 seconds.	Seconds
VolumeIdleTime	The total number of seconds in the period when no read or write operations were submitted.	Seconds
VolumeQueueLength	The number of read and write operation requests waiting to be completed in the period.	Count

Available Dimensions for EBS

The only dimension that EBS sends to CloudWatch is the Volume ID. This means that all available statistics are filtered by Volume ID.

Auto Scaling Metrics and Dimensions

This section discusses the Auto Scaling metrics and dimensions available to CloudWatch.

Available Metrics for Auto Scaling

Metric	Description	Unit
GroupMinSize	The minimum size of the Auto Scaling group.	Count
GroupMaxSize	The maximum size of the Auto Scaling group.	Count

Metric	Description	Unit
GroupDesiredCapacity	The number of instances that the Auto Scaling group attempts to maintain.	Count
GroupInServiceInstances	The number of instances that are running as part of the Auto Scaling group. This metric does not include instances that are pending or terminating.	Count
GroupPendingInstances	The number of instances that are pending. A pending instance is not yet in service. This metric does not include instances that are in service or terminating.	Count
GroupTerminatingInstances	The number of instances that are in the process of terminating. This metric does not include instances that are in service or pending.	Count
GroupTotalInstances	The total number of instances in the Auto Scaling group. This metric identifies the number of instances that are in service, pending, and terminating.	Count

Available Dimensions for Auto Scaling

The only dimension that Auto Scaling sends to CloudWatch is the name of the Auto Scaling group. This means that all available statistics are filtered by Auto Scaling group name.

ELB Metrics and Dimensions

This section discusses the Elastic Load Balancing (ELB) metrics and dimensions available to CloudWatch.

Available Metrics for ELB

Metric	Description	Unit
Latency	Time elapsed after the request leaves the load balancer until it receives the corresponding response. Valid Statistics: Minimum Maximum Average Count	Seconds
RequestCount	The number of requests handled by the load balancer.	Count

Metric	Description	Unit
HealthyHostCount	The number of healthy instances registered with the load balancer in a specified availability zone. Healthy instances are those that have not failed more health checks than the value of the unhealthy threshold. Constraints: You must provide both <code>LoadBalancerName</code> and <code>AvailabilityZone</code> dimensions for this metric. Valid Statistics: Minimum Maximum Average	Count
UnHealthyHostCount	The number of unhealthy instances registered with the load balancer. These are instances that have failed more health checks than the value of the unhealthy threshold. Constraints: You must provide both <code>LoadBalancerName</code> and <code>AvailabilityZone</code> dimensions for this metric. Valid Statistics: Minimum Maximum Average	Count
HTTPCode_ELB_4XX	Count of HTTP response codes generated by ELB that are in the 4xx (client error) series. Valid Statistics: Sum	Count
HTTPCode_ELB_5XX	Count of HTTP response codes generated by ELB that are in the 5xx (server error) series. ELB can generate 5xx errors if no back-end instances are registered, no healthy back-end instances, or the request rate exceeds ELB's current available capacity. This response count does not include any responses that were generated by back-end instances. Valid Statistics: Sum	Count
HTTPCode_Backend_2XX	Count of HTTP response codes generated by back-end instances that are in the 2xx (success) series. Valid Statistics: Sum	Count

Metric	Description	Unit
HTTPCode_Backend_3XX	Count of HTTP response codes generated by back-end instances that are in the 3xx (user action required) series. Valid Statistics: Sum	Count
HTTPCode_Backend_4XX	Count of HTTP response codes generated by back-end instances that are in the 4xx (client error) series. This response count does not include any responses that were generated by ELB. Valid Statistics: Sum	Count
HTTPCode_Backend_5XX	Count of HTTP response codes generated by back-end instances that are in the 5xx (server error) series. This response count does not include any responses that were generated by ELB. Valid Statistics: Sum	Count

Available Dimensions for ELB

You can use the currently available dimensions for ELB to refine the metrics returned by a query. For example, you could use `HealthyHostCount` and dimensions `LoadBalancerName` and `AvailabilityZone` to get the average number of healthy instances behind the specified load balancer within the specified Availability Zone for a given period of time.

You can aggregate ELB data along any of the following dimensions shown in the following table.

Metric	Description
<code>LoadBalancerName</code>	Limits the metric data to instances that are connected to the specified load balancer.
<code>AvailabilityZone</code>	Limits the metric data to load balancers in the specified availability zone.

CloudWatch Tasks

This section details the tasks you can perform using CloudWatch.

This section expands on the basic concepts presented in the preceding section (see [CloudWatch Overview](#) and includes procedures for using CloudWatch. This section also shows you how to view metrics that Eucalyptus services provide to CloudWatch and how to publish custom metrics with CloudWatch.

Configuring Monitoring

This section describes how to enable and disable monitoring for your cloud resources.

Enable Monitoring

This section describes steps for enabling monitoring on your cloud resources.

To enable monitoring on your resources, following the steps for your resource.

Enable monitoring for an instance

- To enable monitoring for a running instance, enter the following command:

```
euca-monitor-instances [instance_id]
```

- To enable monitoring when you launch an instance, enter the following command:

```
euca-run-instances [image_id] -k gsg-keypair --monitor
```

Enable monitoring for a scaling group

- To enable monitoring for an existing Auto Scaling group:
 - Create a launch configuration with `--monitoring-enabled` option.
 - Make a `euscale-update-auto-scaling-group` request to update your Auto Scaling group with the launch configuration you created in the previous step. Auto Scaling will enable monitoring for new instances that it creates.
 - Choose one of the following actions to deal with all existing instances in the Auto Scaling group:

To ...	Do this ...
Preserve existing instances	Make a <code>euca-monitor-instances</code> request for all existing instances to enable monitoring.
Terminate existing instances	Make a <code>euscale-terminate-instance-in-auto-scaling-group</code> request for all existing instances. Auto Scaling will use the updated launch configuration to create replacement instances with monitoring enabled.

- To enable monitoring when you create a new Auto Scaling group:
 - Create a launch configuration with `--monitoring-enabled` option.

Enable monitoring for a load balancer

Elastic Load Balancing (ELB) sends metrics and dimensions for all load balancers to CloudWatch. By default, you do not need to specifically enable monitoring.

Important: ELB only sends CloudWatch metrics when requests are sent through the load balancer. If there are no requests or data for a given metric, ELB does not report to CloudWatch. If there are requests sent through the load balancer, ELB measures and sends metrics for that load balancer in 60-second intervals.

Disable Monitoring

This section describes steps for disabling monitoring on your cloud resources.

To disable monitoring on your resources, following the steps for your resource.

Disable monitoring for an instance

- To disable monitoring for a running instance, enter the following command:

```
euca-unmonitor-instances [instance_id]
```

Disable monitoring for a scaling group

- To enable monitoring for an existing Auto Scaling group:
 - Create a launch configuration with `--monitoring-disabled` option.
 - Make a `euscale-update-auto-scaling-group` request to update your Auto Scaling group with the launch configuration you created in the previous step. Auto Scaling will disable monitoring for new instances that it creates.
 - Choose one of the following actions to deal with all existing instances in the Auto Scaling group:

To ...	Do this ...
Preserve existing instances	Make a <code>euca-unmonitor-instances</code> request for all existing instances to disable monitoring.
Terminate existing instances	Make a <code>euscale-terminate-instance-in-auto-scaling-group</code> request for all existing instances. Auto Scaling will use the updated launch configuration to create replacement instances with monitoring disabled.

- To enable monitoring when you create a new Auto Scaling group:
 - Create a launch configuration with `--monitoring-disabled` option.

Disable monitoring for a load balancer

There is no way to disable monitoring for a load balancer.

Viewing and Publishing Metrics

This section describes how to view Eucalyptus metrics as well as how to publish your own metrics.

List Available Metrics

You can list available metrics via `Euca2ools`.

To list available metrics:

Enter the following command.

```
euwatch-list-metrics
```

Eucalyptus returns a listing of all metrics, as shown in the following partial example output:

```
Metric Name      Namespace      Dimensions
CPUUtilization   AWS/EC2        {InstanceId=i-5431413d}
CPUUtilization   AWS/EC2        {InstanceType=m1.medium}
DiskReadBytes     AWS/EC2        {InstanceId=i-1d3d4d74}
DiskReadBytes     AWS/EC2        {InstanceType=m1.medium}
DiskReadOps       AWS/EC2        {InstanceId=i-d3c8baba}
DiskReadOps       AWS/EC2        {InstanceType=m1.medium}
DiskWriteBytes    AWS/EC2        {InstanceId=i-6732420e}
DiskWriteBytes    AWS/EC2        {InstanceType=m1.medium}
DiskWriteOps      AWS/EC2        {InstanceId=i-e03d4d89}
DiskWriteOps      AWS/EC2        {InstanceType=m1.medium}
NetworkIn         AWS/EC2        {InstanceId=i-e0304089}
NetworkIn         AWS/EC2        {InstanceType=m1.medium}
NetworkOut        AWS/EC2        {InstanceId=i-69334300}
NetworkOut        AWS/EC2        {InstanceType=m1.medium}
StatusCheckFailed AWS/EC2        {InstanceId=i-6f8418e6}
StatusCheckFailed AWS/EC2        {InstanceType=m1.medium}
StatusCheckFailed_Instance AWS/EC2 {InstanceId=i-6f8418e6}
StatusCheckFailed_Instance AWS/EC2 {InstanceType=m1.medium}
StatusCheckFailed_System AWS/EC2 {InstanceId=i-6f8418e6}
StatusCheckFailed_System AWS/EC2 {InstanceType=m1.medium}
```

Get Statistics for a Metric

You can get statistics for metrics via `Euca2ools`.

To get statistics for a metric:

Enter the following command.

```
euwatch-get-stats -n NAMESPACE -s STAT1,STAT2,...
                  [--dimensions KEY1=VALUE1,KEY2=VALUE2,...]
```

```
[--start-time YYYY-MM-DDThh:mm:ssZ]
[--end-time YYYY-MM-DDThh:mm:ssZ] [--period SECONDS]
[--unit UNIT] [--show-empty-fields] [-U URL]
[--region USER@REGION] [-I KEY_ID] [-S KEY]
[--security-token TOKEN] [--debug] [--debugger]
[--version] [-h]
METRIC
```

The following example returns the average CPU utilization for the i-c08804a9 instance at one hour resolution.

```
euwatch-get-stats --namespace "AWS/EC2" --statistics "Average" \
--dimensions "InstanceId=i-c08804a9" --start-time
2016-12-14T23:00:00.000Z \
--end-time 2016-12-15T23:00:00.000Z --period 3600 CPUUtilization
```

The following example returns CPU utilization for all of your cloud's instances.

```
euwatch-get-stats --namespace "AWS/EC2" --statistics
"Average,Minimum,Maximum" \
--start-time 2016-02-14T23:00:00.000Z --end-time
2016-03-14T23:00:00.000Z \
--period 3600 CPUUtilization
```

Publish Custom Metrics

CloudWatch allows you to publish your own metrics, such as application performance, system health, or customer usage.

Publish a single data point

To publish a single data point for a new or existing metric, call `euwatch-put-data` with one value and time stamp. For example, the following actions each publish one data point:

```
euwatch-put-data --metric-name PageViewCount --namespace "TestService" --value
2 --timestamp 2011-03-14T12:00:00.000Z
euwatch-put-data --metric-name PageViewCount --namespace "TestService" --value
4 --timestamp 2011-03-14T12:00:01.000Z
euwatch-put-data --metric-name PageViewCount --namespace "TestService" --value
5 --timestamp 2011-03-14T12:00:02.000Z
```

You can publish data points with time stamps as granular as one-thousandth of a second. However, CloudWatch aggregates the data to a minimum granularity of 60 seconds. For example, the `PageViewCount` metric from the previous examples contains three data points with time stamps just seconds apart. CloudWatch aggregates the three data points because they all have time stamps within a 60-second period.

CloudWatch uses 60-second boundaries when aggregating data points. For example, CloudWatch aggregates the data points from the previous example because all three data points fall within the 60-second period that begins at 2011-03-14T12:00:00.000Z and ends at 2011-03-14T12:00:59.999Z.

Publish statistic sets

You can also aggregate your data before you publish to CloudWatch. When you have multiple data points per minute, aggregating data minimizes the number of calls to `euwatch-put-data`. For example, instead of calling `euwatch-put-data` multiple times for three data points that are within three seconds of each other, you can aggregate the data into a statistic set that you publish with one call:

```
euwatch-put-data --metric-name PageViewCount --namespace "TestService"
-s "Sum=11,Minimum=2,Maximum=5,SampleCount=3" --timestamp
2011-03-14T12:00:00.000
```

Publish the value zero

When your data is more sporadic and you have periods that have no associated data, you can choose to publish the value zero (0) for that period or no value at all. You might want to publish zero instead of no value if you use periodic

calls to `PutMetricData` to monitor the health of your application. For example, you can set an Amazon CloudWatch alarm to notify you if your application fails to publish metrics every five minutes. You want such an application to publish zeros for periods with no associated data.

You might also publish zeros if you want to track the total number of data points or if you want statistics such as minimum and average to include data points with the value 0.

Modify Metric Polling Timing

You can modify metrics timing and reporting defaults.

When using the default CloudWatch properties, metrics reporting can take around 15 minutes:

1. 5 minutes to receive a sensor data point for an instance.
2. 5 more minutes to receive a second sensor data point for an instance.
3. 1 more minute to calculate the difference between these two and send a single data point to CloudWatch.
4. 1 more minute for CloudWatch to put the data in the database, making it available for a `euwatch-get-stats` call.
5. 5 more minutes for `euwatch-list-metrics` info to be available in the database.

Note: The above workflow is sequential and cumulative.

The sensor data point timing values can be shortened by changing variables in the CLC.

Important: These changes will increase network traffic as polling will be done more frequently.

To modify metrics defaults:

1. Modify the default polling interval CLC variable to a number less than 5.

```
cloud.monitor.default_poll_interval_mins
```

This is how often the CLC sends a request to the CC for sensor data. Default value is 5 minutes.

2. Modify the history size CLC variable to a number less than 5.

```
cloud.monitor.history_size
```

This is how many data value samples are sent in each sensor data request. The default value is 5. The frequency requests is either 1 minute (if the `cloud.monitor.default_poll_interval_mins` is 1 minute) or half the value of `cloud.monitor.default_poll_interval_mins` if that value is greater).

So by default, with a `cloud.monitor.default_poll_interval_mins` of 5 minutes and `cloud.monitor.history_size` size of 5, every 5 minutes the CLC asks for the last 5 data points from the CC, which should be timed for every 2.5 minutes (e.g., 2.5 minutes ago, 5 minutes ago, 7.5 minutes ago, and 10 minutes ago).

Note: These values may be skewed a bit based on the time the CC uses.

For more information, see [Eucalyptus Configuration Variables](#).

Configuring Alarms

This section describes how to create, test, and delete an alarm.

Create an Alarm

You can create a CloudWatch alarm using a resource's metric, and then add an action using the action's dedicated Amazon Resource Name (ARN). You can add the action to any alarm state.

Important: Eucalyptus currently only supports actions for executing Auto Scaling policies.

To create an alarm, perform the following step.

Enter the following command:

```
euwatch-put-metric-alarm [alarm_name] --unit Percent --namespace "AWS/EC2"
```

```
-- dimensions "InstanceId=[instance_id]" --statistic [statistic] --metric-name
[metric] --comparison-operator [operator] --threshold [value] --period
[seconds] --evaluation-periods [value] -- alarm-actions [action]
```

For example, the following triggers an Auto Scaling policy if the average CPUUtilization is less than 10 percent over a 24 hour period.

```
euwatch-put-metric-alarm test-Alarm --unit Percent --namespace "AWS/EC2"
-- dimensions "InstanceId=i-abc123" --statistic Average --metric-name
CPUUtilization
--comparison-operator LessThanThreshold --threshold 10 --period 86400
--evaluation-periods 4 -- alarm-actions
arn:aws:autoscaling::429942273585:scalingPolicy:
12ad560b-58b2-4051-a6d3-80e53b674de4:autoScalingGroupName/testgroup01:
policyName/testgroup01-pol01
```

Test an Alarm

You can test the CloudWatch alarms by temporarily changing the state of your alarm to "ALARM" using the command: `euwatch-set-alarm-state`.

```
euwatch-set-alarm-state --alarm-name TestAlarm --state ALARM
```

Delete an Alarm

To delete an alarm, perform the following step.

- Enter the following command:

```
euwatch-delete-alarms [alarm_name]
```

For example, to delete an alarm named `TestAlarm` enter:

```
euwatch-delete-alarms TestAlarm
```

Using Object Storage

Scalable object storage is composed of two parts: the object storage gateway and the object storage backend. This section explains storage and how to access it.

The object storage gateway (OSG) receives user requests and authorizes these requests using the Eucalyptus identity services. For more information about identity services, see [Managing Access](#).

Access Object Storage

You can use your favorite S3 client (for example, `s3curl`) to interact with Eucalyptus.

To access object storage:

Replace your `S3_URL` with the IP address of the OSG you wish to interact with and the service path with `/services/objectstorage` instead of `/services/Walrus`. For example:

```
S3_URL = http://<OSG IP>:8773/services/objectstorage
```

Note: If you have DNS enabled, you may use the "objectstorage" prefix to access your object storage. Eucalyptus will return a list of IPs that correspond to OSGs that are in the `ENABLED` state.

Using CloudFormation

This topic describes the Eucalyptus implementation of the AWS CloudFormation web service, how CloudFormation works, and some details and examples of how to add CloudFormation to your Eucalyptus deployment.

Why use CloudFormation?

Cloud computing allows for application repeatability and redundancy. This means that you can spin up as many virtual machines as you need, but the application configuration only needs to happen when the images are created. CloudFormation takes this concept to the next level: it allows you to configure an entire set of resources (instances, security groups, user roles and policies, and more) in a single JSON template file. Then you can run all with a single command. So, you don't just get machine repeatability, you get environment repeatability. CloudFormation allows you to clone environments in different cloud setups, as well as giving applications the ability to be set up and torn down in a repeatable manner.

How does CloudFormation Work?

CloudFormation manages a set of resources, called a stack, in batch operations (create, update, or delete). Stacks are described in JSON templates, and can be simple, as the following example:

```
{
  "Resources" : {
    "MyInstance": {
      "Type": "AWS::EC2::Instance",
      "Properties": {
        "ImageId" : "emi-db0b2276"
      }
    }
  }
}
```

This stack creates a single instance, based on the image with ID `emi-db0b2276`. However, this stack is not portable because different clouds might have different image IDs.

CloudFormation allows stack customization through user parameters that are passed in at stack creation time. The following is an example of the template above with a user parameter called `MyImageId`. Changes are in bold.

```
{
  "Parameters": {
    "MyImageId": {
      "Description": "Image id",
      "Type": "String"
    }
  },
  "Resources" : {
    "MyInstance": {
      "Type": "AWS::EC2::Instance",
      "Properties": {
        "ImageId" : { "Ref" : "MyImageId" }
      }
    }
  }
}
```

This stack creates a single instance, but the image ID will be required to be passed in using the command line. For example, the following example uses the `euform-create-stack` command in Euca2ools:

```
euform-create-stack --template-file template.json -p MyImageId=emi-db0b2276
MyStack
```

This command passes the parameter `MyImageId` with value `emi-db0b2276` into the stack creation process using the `-p` flag.

You can also use templates to create multiple resources and associate them with each other. For example, the following template creates an instance with its own security group and ingress rule. Additions are in bold.

```
{
  "Parameters": {
    "MyImageId": {
      "Description": "Image id",
      "Type": "String"
    }
  },
  "Resources" : {
    "MySecurityGroup": {
      "Type": "AWS::EC2::SecurityGroup",
      "Properties": {
        "GroupDescription" : "Security Group with Ingress Rule for
MyInstance",
        "SecurityGroupIngress" : [
          {
            "IpProtocol" : "tcp",
            "FromPort" : "22",
            "ToPort" : "22",
            "CidrIp" : "0.0.0.0/0"
          }
        ]
      }
    },
    "MyInstance": {
      "Type": "AWS::EC2::Instance",
      "Properties": {
        "ImageId" : { "Ref": "MyImageId" },
        "SecurityGroups" : [
          { "Ref" : "MySecurityGroup" }
        ]
      }
    }
  }
}
```

Templates can be more complicated than the ones shown above, but CloudFormation allows many resources to be deployed in one operation. Resources from most Eucalyptus services are supported.

CloudFormation Requirements

To run CloudFormation on Eucalyptus, you need the following:

- A running Eucalyptus cloud, version 4.0 or later, with at least one Cloud Controller, Node Controller, and Cluster Controller up, running and registered
- At least one active running service of each of the following: CloudWatch, AutoScaling, Load Balancing, Compute, and IAM
- A registered active CloudFormation service

Supported Resources

The following resources are supported by CloudFormation in Eucalyptus.

Resource	Description
AWS::AutoScaling::AutoScalingGroup	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except: HealthCheckType, Tags, and VpcZoneIdentifier.
AWS::AutoScaling::LaunchConfiguration	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except AssociatePublicIpAddress.
AWS::AutoScaling::ScalingPolicy	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::CloudFormation::WaitCondition	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::CloudFormation::WaitConditionHandle.	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::CloudWatch::Alarm	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::CustomerGateway	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::DHCPOptions	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::EIP	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except Domain.
AWS::EC2::EIPAssociation	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except: AllocationId, NetworkInterfaceId, and PrivateIpAddress.
AWS::EC2::Instance	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except: NetworkInterfaces, SecurityGroupIds, SourceDestCheck, Tags, and Tenancy. All other properties are forwarded to the Compute service internally but VPC is not implemented so VPC oriented properties are likely ignored there.
AWS::EC2::InternetGateway	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::NetworkAcl	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::NetworkAclEntry	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::NetworkInterface	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::Route	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::RouteTable	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.

Resource	Description
AWS::EC2::SecurityGroup	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except: SecurityGroupEgress, Tags, and VpcId.
AWS::EC2::SecurityGroupEgress	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::SecurityGroupIngress	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except SourceSecurityGroupId.
AWS::EC2::Subnet	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::SubnetNetworkAclAssociation	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::SubnetRouteTableAssociation	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::Volume	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except: HealthCheckType and Tags.
AWS::EC2::VolumeAttachment	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::VPC	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::VPCDHCPOptionsAssociation	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::EC2::VPCGatewayAttachment	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::ElasticLoadBalancing::LoadBalancer	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except: AccessLoggingPolicy, ConnectionDrainingPolicy, CrossZone, Policies.InstancePorts, and Policies.LoadBalancerPorts. All other properties are passed through to the LoadBalancing service internally but some features are not implemented so properties may be ignored there.
AWS::IAM::AccessKey	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported except Serial.
AWS::IAM::Group	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::IAM::InstanceProfile	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::IAM::Policy	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::IAM::Role	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.

Resource	Description
AWS::IAM::User	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::IAM::UserToGroupAddition	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.
AWS::S3::Bucket	All properties in the Template Reference section of the AWS CloudFormation User Guide are supported.

CloudFormation Registration

To register CloudFormation for your cloud, enter the following command:

```
euserv-register-service -t CloudFormation -h CLOUD_FORMATION_HOST_IP
SVCINSTANCE
```

For example:

```
euserv-register-service -t CloudFormation -h 203.0.113.13 cfn
```

Eucalyptus returns information similar to the following:

```
Created new partition 'cfn'
SERVICE    cloudformation    cfn    cfn http://203.0.113.13:8773/services/
CloudFormation    arn:euca:bootstrap:cfn:cloudformation:cfn/
```

The CloudFormation service will be shown when you run `euserv-describe-services`.

WSDL URL

The service WSDL URL for CloudFormation is of the form:

```
http://<host-ip>:8773/services/CloudFormation
```

The services path may not be necessary if DNS is enabled, it may look something like this:

```
http://cloudformation.g-19-10.autoqa.qa1.eucalyptus-systems.com:8773/
```

CloudFormation follows the same convention as the other [user-facing services](#).

CloudFormation Run Options

You can run CloudFormation using Euca2ools, the AWS SDK for Java, the AWS command line interface, and Boto.

Euca2ools

For information about Euca2ools CloudFormation commands, see [CloudFormation-Compatible Commands](#).

AWS SDK for Java

The AWS SDK has data types and command structures that are generally a one-to-one match to what is defined in the AWS API documentation. For more information about the SDK API, go to the [AWS SDK for Java API Reference](#).

The following is an example of a describe stacks call.

```
import com.amazonaws.services.cloudformation.AmazonCloudFormationClient;
import com.amazonaws.services.cloudformation.model.DescribeStacksRequest;
import com.amazonaws.services.cloudformation.model.DescribeStacksResult;
import com.amazonaws.services.cloudformation.model.Output;
import com.amazonaws.services.cloudformation.model.Parameter;
import com.amazonaws.services.cloudformation.model.Stack;
import com.amazonaws.services.cloudformation.model.Tag;
```

```

public class DescribeStacksTest {
    private static final String AWS_ACCESS_KEY = ...; // Don't really hard-code
    creds
    private static final String AWS_SECRET_KEY = ...; // Don't really hard-code
    creds

    private static final BasicAWSCredentials CREDENTIALS = new BasicAWSCredentials(
        ACCESS_KEY, SECRET_KEY);
    private static final String HOST = "10.111.1.134:8773";

    private static final AmazonCloudFormationClient CLOUDFORMATION_CLIENT() {
        AmazonCloudFormationClient cf = new AmazonCloudFormationClient(CREDENTIALS);
        cf.setEndpoint("http://" + HOST + "/services/CloudFormation/");
        return cf;
    }

    public static void main(String[] args) {

        describeStacksRequest = new DescribeStacksRequest();
        describeStacksRequest.setStackName("MyStack");
        DescribeStacksResult describeStacksResult =
            cloudFormation.describeStacks(describeStacksRequest);
        printStackResult(describeStacksResult);
    }

    private static void printStackResult(DescribeStacksResult
        describeStacksResult) {
        System.out.println("describeStacksResult.getNextToken()=" +
            describeStacksResult.getNextToken());
        for (Stack stack: describeStacksResult.getStacks()) {
            System.out.println("stack.getDescription()="+stack.getDescription());
            for (String capability: stack.getCapabilities()) {
                System.out.println("capability="+capability);
            }
            System.out.println("stack.getCreationTime()="+stack.getCreationTime());
            System.out.println("stack.getDescription()="+stack.getDescription());

            System.out.println("stack.getDisableRollback()="+stack.getDisableRollback());

            System.out.println("stack.getLastUpdatedTime()="+stack.getLastUpdatedTime());
            for (String capability: stack.getCapabilities()) {
                System.out.println("capability="+capability);
            }
            for (String notificationARN: stack.getNotificationARNs()) {
                System.out.println("notificationARN="+notificationARN);
            }
            for (Output output: stack.getOutputs()) {

                System.out.println("output.getDescription()="+output.getDescription());
                System.out.println("output.getOutputKey()="+output.getOutputKey());

                System.out.println("output.getOutputValue()="+output.getOutputValue());
            }
            for (Parameter parameter: stack.getParameters()) {

                System.out.println("parameter.getParameterKey()="+parameter.getParameterKey());

                System.out.println("parameter.getParameterValue()="+parameter.getParameterValue());
            }
            System.out.println("stack.getStackId()="+stack.getStackId());
            System.out.println("stack.getStackName()="+stack.getStackName());
            System.out.println("stack.getStackStatus()="+stack.getStackStatus());
        }
    }
}

```

```

System.out.println("stack.getStackStatusReason()="+stack.getStackStatusReason());
    for (Tag tag: stack.getTags()) {
        System.out.println("tag.getKey()="+tag.getKey());
        System.out.println("tag.getValue()="+tag.getValue());
    }

System.out.println("stack.getTimeoutInMinutes()="+stack.getTimeoutInMinutes());
}
}
}

```

Eucalyptus returns all of the fields, and the stack name is passed in to the call.

For more information about the AWS SDK for Java, go to <http://aws.amazon.com/sdkforjava/>.

AWS Command Line Interface

You can use the AWS command line interface (CLI) with Eucalyptus CloudFormation. For example, the following command describes a stack:

```
aws --endpoint http://10.111.1.134:8773/services/CloudFormation cloudformation
describe-stacks
```

Credential information is either also passed using flags or stored in a file referenced by the `AWS_CONFIG_FILE` environment variable. Results from the previous command are in JSON:

```

{
  "Stacks": [
    {
      "StackId": "arn:aws:cloudformation::299958418681:stack/MyStack/
c70b9e4e-fcd5-47e6-b1ae-68cdb8f9f22c",
      "LastUpdatedTime": "2014-05-30T05:19:44.085Z",
      "Parameters": [
        {
          "ParameterValue": "emi-db0b2276",
          "ParameterKey": "MyImageId"
        }
      ],
      "Tags": [],
      "Outputs": [],
      "StackStatusReason": "Complete!",
      "CreationTime": "2014-05-30T05:19:22.412Z",
      "Capabilities": [],
      "StackName": "MyStack",
      "NotificationARNs": [],
      "StackStatus": "CREATE_COMPLETE",
      "DisableRollback": false
    }
  ]
}

```

For more information about the AWS CLI, go to <http://docs.aws.amazon.com/cli/latest/reference/cloudformation/index.html>.

Boto

Boto is a Python API that calls the AWS web service API, and is well documented. The following snippet accesses the base CloudFormation "cf" object:

```

import boto
from boto.regioninfo import RegionInfo
region = RegionInfo()
region.endpoint = "10.111.1.134"

```

```
region.name = "eucalyptus"
cfn = boto.connect_cloudformation(region=region, port=8773, path="/services/CloudFormation", is_secure=False)
```

For more information about Boto, go to <https://github.com/boto/boto>.

CloudFormation Use Case

This topic describes a use case for creating a stack, checking the stack progress, and deleting the stack.

For this use case, we will use the following template:

```
{
  "Parameters": {
    "MyImageId": {
      "Description": "Image id",
      "Type": "String"
    },
    "MyKeyPair": {
      "Description": "Key Pair",
      "Type": "String"
    }
  },
  "Resources": {
    "MySecurityGroup": {
      "Type": "AWS::EC2::SecurityGroup",
      "Properties": {
        "GroupDescription": "Security Group with Ingress Rule for MyInstance",
        "SecurityGroupIngress": [
          {
            "IpProtocol": "tcp",
            "FromPort": "22",
            "ToPort": "22",
            "CidrIp": "0.0.0.0/0"
          }
        ]
      }
    },
    "MyInstance": {
      "Type": "AWS::EC2::Instance",
      "Properties": {
        "ImageId": { "Ref": "MyImageId" },
        "SecurityGroups": [
          { "Ref": "MySecurityGroup" }
        ],
        "KeyName": { "Ref": "MyKeyPair" }
      }
    }
  }
}
```

This template creates an instance with a security group that allows global SSH access (port 22), but uses a keypair to log in. It requires two parameters, `MyImageId`, which is the image ID of the instance to create, and `MyKeyPair`, which is the name of the keypair to use to log in with. You can use both values with the `euca-run-instances` command to create an instance manually (for example, `euca-run-instances -k mykey emi-db0b2276`) so the arguments needed here are standard instance arguments.

The steps to run this template through the system are explained in the following steps.

Important: These steps require that you have an available image (run `euca-describe-images` to verify) and that the CloudFormation service is running (run `euserv-describe-services` to verify).

1. Verify connectivity to the CloudFormation service.

```
euform-describe-stacks
```

You should not see anything returned, including any errors.

2. Create a file called `ex_template.json` that contains the following content:

```
{
  "Parameters": {
    "MyImageId": {
      "Description": "Image id",
      "Type": "String"
    },
    "MyKeyPair": {
      "Description": "Key Pair",
      "Type": "String"
    }
  },
  "Resources": {
    "MySecurityGroup": {
      "Type": "AWS::EC2::SecurityGroup",
      "Properties": {
        "GroupDescription": "Security Group with Ingress Rule for MyInstance",
        "SecurityGroupIngress": [
          {
            "IpProtocol": "tcp",
            "FromPort": "22",
            "ToPort": "22",
            "CidrIp": "0.0.0.0/0"
          }
        ]
      }
    },
    "MyInstance": {
      "Type": "AWS::EC2::Instance",
      "Properties": {
        "ImageId": { "Ref": "MyImageId" },
        "SecurityGroups": [
          { "Ref": "MySecurityGroup" }
        ],
        "KeyName": { "Ref": "MyKeyPair" }
      }
    }
  }
}
```

3. Create a keypair.

```
euca-create-keypair myKey > myKey.pem
```

4. Set the permissions on the keypair.

```
chmod 0600 myKey.pem
```

5. Find what resources have been created., run the command and the `euca-describe-groups` commands. Make note of the output for later.

- a) Run:

```
euca-describe-instances
```

Note the output for later use.

- b) Run:

```
euca-describe-groups
```

Note the output for later use.

6. Create the stack.

```
euform-create-stack --template-file ex_template.json -p
MyImageId=<image_id>, MyKeyPair=
myKey MyStack
```

Eucalyptus returns output similar to the following:

```
arn:aws:cloudformation::299958418681:stack/MyStack/28fd422b-0836-4374-ade2-
eddab2fab3e3
```

7. Run the checks you want on your stack.

- Check the status of the stack.

```
euform-describe-stack
STACK    MyStack    CREATE_COMPLETE    Complete!
2014-05-30T18:45:54.695Z
```

- Check the stack at any time to see all the events that have occurred during the stack lifecycle.

```
euform-describe-stack-events MyStack

22            22    FROM        CIDR        0.0.0.0/0    ingress
```

8. Try to SSH into the instance.

```
ssh -i myKey.pem root@10.111.101.87
```

Tip: Username might depend on the instance type, and might be root or ubuntu or ec2-user.

9. Delete the stack.

```
euform-delete-stack MyStack
```

You can run `euca-describe-stacks` and all the other describe commands to check the progress until the delete is complete.

Make sure the instance is terminated and that the security group no longer exists.

CloudFormation Templates

This topic details templates that have been tested with Eucalyptus.

AccessKeys.template

```
{
  "AWSTemplateFormatVersion": "2010-09-09",
  "Parameters": {
    "Username": {
      "Description": "Username",
      "Type": "String"
    }
  },
  "Resources": {
    "Key1": {
      "Type": "AWS::IAM::AccessKey",
      "Properties": {
        "UserName": { "Ref": "Username" },
        "Serial": "1",
        "Status": "Active"
      }
    },
    "Key2": {
      "Type": "AWS::IAM::AccessKey",
      "Properties": {
```

```

        "UserName":{"Ref":"Username"},
        "Serial":"1",
        "Status":"Inactive"
    }
},
"Outputs":{
    "Key1AK":{
        "Value":{"Ref":"Key1"}
    },
    "Key1SK":{
        "Value":{"Fn::GetAtt":["Key1","SecretAccessKey"]}
    },
    "Key2AK":{
        "Value":{"Ref":"Key2"}
    },
    "Key2SK":{
        "Value":{"Fn::GetAtt":["Key2","SecretAccessKey"]}
    }
}
}

```

AutoscalingGroupsAndCloudWatchAlarm.template

```

{
    "AWSTemplateFormatVersion":"2010-09-09",
    "Parameters":{
        "ImageId":{
            "Description":"Image id",
            "Type":"String"
        }
    },
    "Resources":{
        "LaunchConfig":{
            "Type":"AWS::AutoScaling::LaunchConfiguration",
            "Properties":{
                "ImageId":{"Ref":"ImageId"},
                "InstanceType":"m1.small",
                "BlockDeviceMappings":[
                    {
                        "DeviceName":"/dev/sdc",
                        "VirtualName":"ephemeral10",
                        "Ebs":{"VolumeSize":"10"}
                    }
                ],
                "SecurityGroups":[{"Ref":"InstanceSecurityGroup"}]
            }
        },
        "ASG1":{

ElasticIP.template

This template attaches an [elastic IP](#) to a new and existing instance. You must pass along the existing instance ID.

```

{
  "AWSTemplateFormatVersion":"2010-09-09",
  "Description":"Create an EC2 instance running a specified EMI and some
elastic IP addresses.",
  "Parameters":{
    "ImageId":{
      "Description":"Image id",
      "Type":"String"
    },
    "OtherInstanceId":{
      "Description":"Other instance id",

```

```

    "Type": "String"
  },
  "Resources": {
    "Ec2Instance1": {
      "Type": "AWS::EC2::Instance",
      "Properties": {
        "ImageId": {"Ref": "ImageId"}
      }
    },
    "EIP1": {
      "Type": "AWS::EC2::EIP",
      "Properties": {
        "InstanceId": {"Ref": "Ec2Instance1"}
      }
    },
    "EIP2": {
      "Type": "AWS::EC2::EIP",
      "Properties": {
      }
    },

IAM_Users_Groups_and_Policies.template

```

{
  "AWSTemplateFormatVersion":"2010-09-09",
  "Description":"AWS CloudFormation Sample Template
IAM_Users_Groups_and_Policies: Sample template showing how to create IAM
users, groups and policies. It creates a single user that is a member of a
users group and an admin group. The groups each have different IAM policies
associated with them. Note: This example also creates an AWSAccessKeyId/
AWSecretKey pair associated with the new user. The example is somewhat
contrived since it creates all of the users and groups, typically you would
be creating policies, users and/or groups that contain references to existing
users or groups in your environment. Note that you will need to specify
the CAPABILITY_IAM flag when you create the stack to allow this template to
execute. You can do this through the AWS management console by clicking on
the check box acknowledging that you understand this template creates IAM
resources or by specifying the CAPABILITY_IAM flag to the cfn-create-stack
command line tool or CreateStack API call. ",

    }
}

```

Troubleshooting CloudFormation

This topic describes some of the issues that can happen with CloudFormation. It also talks about how you can detect these issues, and offers some ways to fix the issues.

Invalid JSON

JSON must be syntactically valid. For example, if you don't type in the final } character in a template, the `euform-create-stack` command returns an error message.

```

euform-create-stack: error
(ValidationError): Unexpected end-of-
input:
expected close marker for
OBJECT (from [Source:
java.io.StringReader@56b3916d;
line: 1, column: 0]) at [Source:
java.io.StringReader@56b3916d; line:
38,
column : 849]

```

If you see an error like this, there is most likely something syntactically wrong with your JSON template. Some editors can detect things like unbalanced parentheses, but in the worst case you can paste your

template into this URL <http://jsonparseronline.com/> and it will help you find syntax errors.

Invalid Argument

If you try to create, for example, a stack that already exists, you will get a simple error message.

```
euform-create-stack: error
(AlreadyExists): Stack already exists
```

Invalid Reference

If you use an invalid reference to, for example, a resource that doesn't exist, Eucalyptus returns a simple error message.

```
euform-create-stack: error
(ValidationError): Template
format error: Unresolved resource
dependencies [MySecurityGroup2] in
the Resources block of the template>
```

Complex Errors

Not all errors are simple. We recommend that you use `euform-describe-stacks` and `euform-describe-stack-resources` to determine the current state of the stack. If there's an error, it will usually be shown in the `euform-describe-stack-events` output. Otherwise, you will have to dig into the `cloud-output.log` file for further information.

You can also manually delete resources if they are causing issues. If a `euform-delete-stack` fails, you can delete the offending resource and try again.

Using Virtual Private Cloud

Eucalyptus Virtual Private Cloud (VPC) is an implementation of Amazon VPC that allows you to define a logically isolated virtual network that can contain Eucalyptus resources. A virtual network enhances security by allowing you to have fine-grained, explicit control over network gateways, subnets, IP address ranges, and inbound and outbound connectivity. This section of the User Guide covers how Eucalyptus VPC works and how to use it.

Note: For more information about Amazon Virtual Private Cloud, see the [Amazon VPC documentation](#).

How VPC Works

Eucalyptus Virtual Private Cloud (VPC) is an implementation of Amazon VPC that allows you to run instances inside an isolated virtual network that you define. Eucalyptus VPC enables you to have control over subnets, internet gateways, and IP address ranges and allocations inside of this virtual network, as well as the ability to define and use multiple layers of security with security groups.

Default VPCs

Starting with Eucalyptus versions 4.1 and later, when you create an account in your Eucalyptus cloud in VPCMIDO network mode, you get a default VPC with a single public subnet and an attached Internet gateway. All instances that are created in this account that do not explicitly specify a VPC are placed into this default VPC and given a public IP address and behave like 'classic' AWS EC2 instances.

Subnets and IP Addressing

A virtual private cloud (VPC) is a virtual network that is logically isolated from other virtual networks in your Eucalyptus cloud.

Note: For more information about CIDR notation, see the [Classless Inter-Domain Routing](#) article on Wikipedia.

Private IP Addresses

When you create a VPC, you can specify the range of IP addresses for your VPC using Classless Inter-Domain Routing (CIDR) notation. When you launch an instance (VM) in your VPC, you can assign a private IP address to the instance from this IP address range. If you don't explicitly assign a private IP address, one is assigned to the instance for you.

Public IP Addresses

By default, instances launched into the default subnet in your VPC receive a public IP address. This public IP address is assigned from a pool of public IP addresses, and is not associated with your account. This public IP address can't be manually added or removed from the VPC instance. The public IP address is mapped to the instance's private IP address using Network Address Translation (NAT).

You can control whether or not your VPC instances get a public IP address by either enabling/disabling the public IP address attribute of the subnet, or by overriding the subnet's behavior when launching an instance into the VPC.

If you want a persistent IP address for your VPC instance, you can use the `euca-allocate-address` to create an elastic IP address, and then use `euca-associate-address` to assign this address.

Subnets

Once you've created a VPC, you can create one or more subnets inside the VPC. A subnet is simply a logical subdivision of a network of IP addresses. Subnets can be used to enable tighter security, allow separate administration of the network by organization, and enable more efficient network traffic by containing traffic between nodes in a subnet and using route tables for traffic that needs to move between subnets.

Note that subnets in a VPC cannot overlap; and the first four IP addresses and the last IP address are reserved for internal use. For example, of the 16 IP addresses of a /28 subnet, 11 are available for instances; of the 256 IP addresses of a /24 subnet, 251 are available for instances. Subnets must be larger than /28 and smaller than /16.

Note: For more information about subnets, see the [Subnetwork article](#) on Wikipedia.

Understanding VPC Networking Concepts

This section discusses VPC networking concepts and terminology.

Important: This documentation assumes that you have some knowledge of IP addressing, CIDR, route tables, and subnets. See the links included throughout the documentation for more information on these topics.

Domain Name System (DNS)

The Domain Name System (DNS) is an Internet standard that maps unique DNS names (for example: `www.example.com`) to the underlying public IP address (for example: `128.0.0.1`).

Eucalyptus provides a DNS service with your cloud. By default, EC2 classic (EDGE mode) and VPCMIDO mode default subnet instances that are launched in your Eucalyptus cloud are automatically assigned public and private DNS names from the Eucalyptus DNS service.

Elastic Network Interfaces (ENIs)

In Eucalyptus VPC, networking to instances (VMs) is delivered in the form of Elastic Network Interfaces (ENIs). ENIs are virtual network interfaces that can be attached to and/or detached from instances in a VPC.

Attributes of an ENI (private address, public address, Elastic IP, MAC address, security groups, and source/destination check flag) follow the ENI as it is detached from an instance and attached to another instance. An instance in a VPC has a default ENI attached, which is called the primary ENI. The Primary ENI cannot be detached.

Additional ENIs (up to a total of eight) can be attached to instances as needed. ENIs in different subnets can be attached to the same instance, but all ENIs and the instance must reside in the same Availability Zone. Users may need to manually bring up and configure secondary ENIs from within instances.

Route Tables

A route table defines how traffic is directed in your network. Each subnet in your network has to be associated with one (and only one) route table, but a route table can have multiple subnets associated with it. A default route table (which simply contains a local route that allows communication within the VPC) is automatically created for you when you create your VPC. New subnets will get this route table by default, but you can replace it with a custom route table that enables you to explicitly control subnet traffic.

Note: For more information on route tables, see the [Routing table article](#) on Wikipedia.

Internet Gateways

An Internet gateway is an object that runs inside of your VPC and provides communication between VPC instances and the Internet.

To use an Internet gateway in your VPC, you attach the gateway to your VPC, make sure your route tables direct Internet traffic to the Internet gateway, and configure your security groups to allow traffic through.

By default, instances loaded into any non-default VPC have private IP addresses (so they can communicate with other instances in the same VPC), but they do not have public IP addresses. For an instance to be able to communicate with the Internet gateway, it must have an associated public IP address. The default VPC comes with a pre-configured Internet gateway, and all instances that are launched into the default subnet receive a public IP address, so these instances have Internet access.

Network Address Translation (NAT) Gateways

NAT Gateways enable instances in private VPC subnets to initiate communication with the Internet (and receive responses), but prevents connections to be initiated from the Internet. Traffic bound to the Internet from instances in private subnets should be directed to a NAT gateway (through the use of route tables), which will translate the source address to its own Elastic IP and route it to the Internet. The destination will send a response back to the Elastic IP (i.e., the NAT gateway), where the address translation will be reversed and delivered to the originating private IP.

NAT Gateways should be created in public VPC subnets, and have an Elastic IP associated. Private VPC subnets should have its route table manually updated to direct Internet-bound traffic to a NAT gateway.

VPC Security Concepts

This section discusses VPC security concepts and terminology.

Security Groups

A security group is a mechanism that allows you to control inbound and outbound traffic for your VPC. A security group has rules that specify what kinds of traffic are allowed in and out of instances (VMs) running in your VPC.

A VPC comes with a default security group that allows inbound traffic from other instances assigned to the same security group, and allows all outbound traffic. You can change the rules for the default security group, but you can't delete it.

If you don't specify a security group when you launch an instance in your VPC, the instance will be associated with the default security group.

User Guide History

This section contains information about changes to the user documentation in this release.

Section / Topic	Description of Change	Date Changed
Updates	Minor updates and corrections for 4.4 release.	March 2017
